

## Features/Benefits

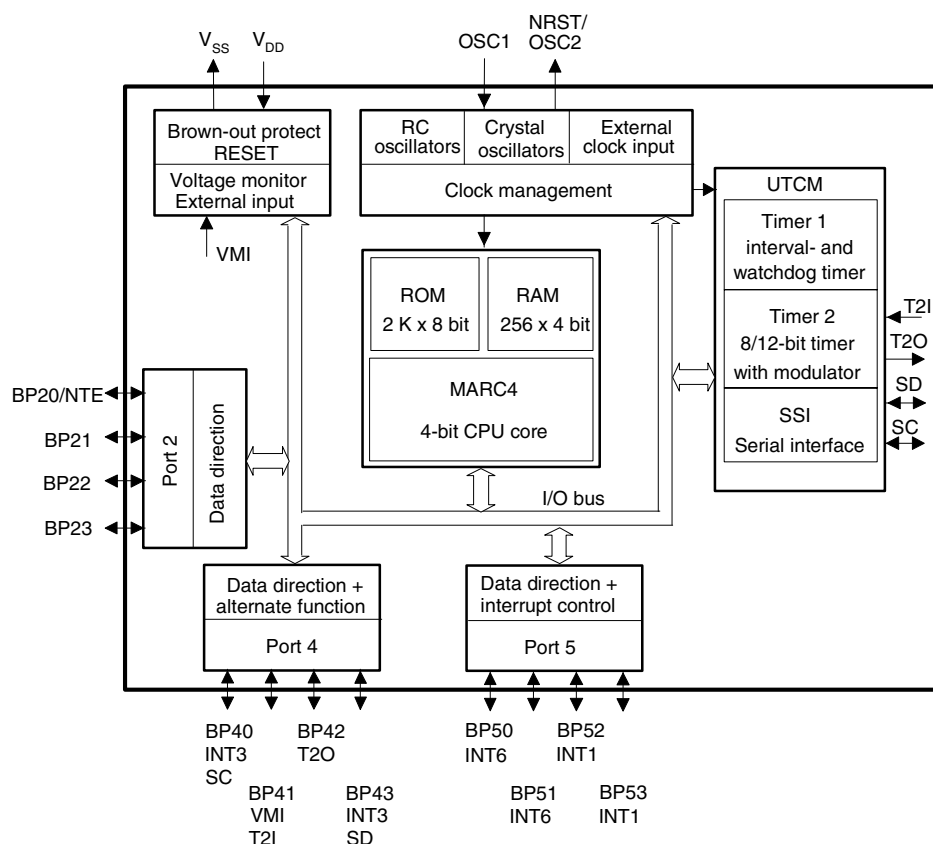

- Extended Temperature Range for Very High Temperature up to 125°C
- Very Low Power Consumption in Active, Power-down and Sleep Mode
- 2-Kbyte ROM, 256 × 4-bit RAM
- 12 Bi-directional I/Os
- Up to 6 External/Internal Interrupt Sources
- Multifunction Timer/Counter
- Programmable System-clock with Prescaler and Five Different Clock Sources
- Wide Supply-voltage Range (1.8 V to 6.5 V)
- Very Low Sleep Current (< 1 µA)
- Synchronous Serial Interface (2-wire, 3-wire)
- Watchdog, POR and Brown-out Function
- Voltage Monitoring Inclusive Lo\_BAT Detect
- Flash Controller ATAM893 Available (SSO20)

## Description

The ATAR080-D is a member of Atmel's family of 4-bit single-chip microcontrollers. It contains ROM, RAM, parallel I/O ports, one 8-bit programmable multifunction timer/counter with modulator function, voltage supervisor, interval timer with watchdog function and a sophisticated on-chip clock generation with external clock input, integrated RC-, 32-kHz and 4-MHz crystal-oscillators.

## Introduction

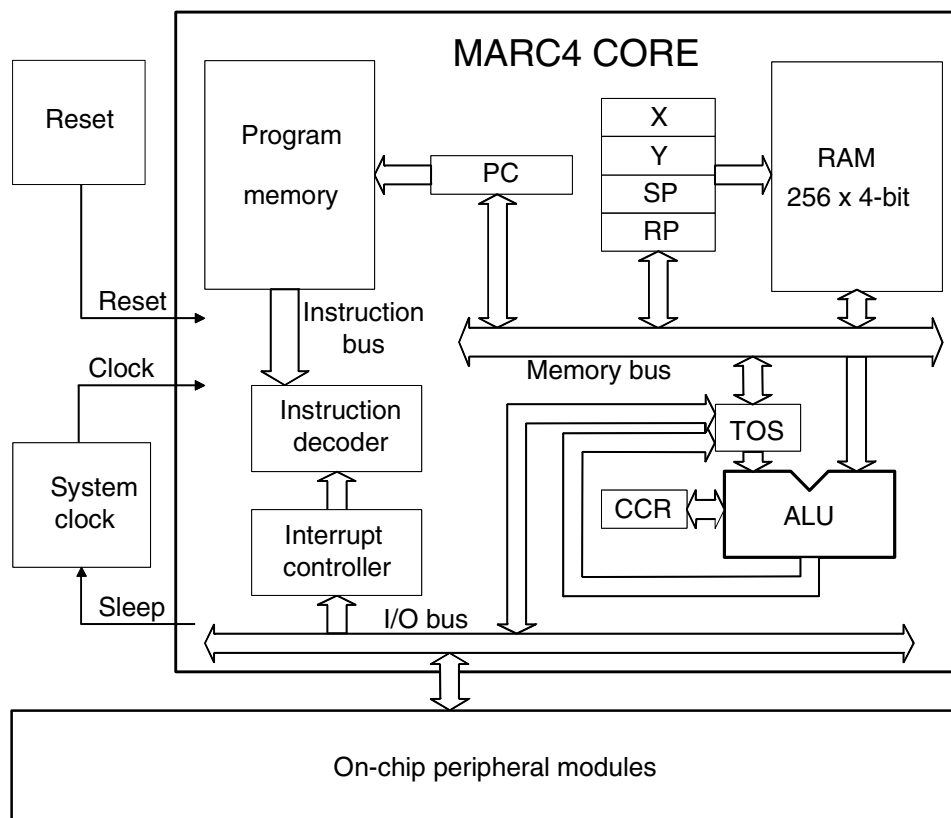

The ATAR080-D is a member of Atmel's family of 4-bit single-chip microcontrollers. They contain ROM, RAM, parallel I/O ports, one 8-bit programmable multifunction timer/counter, voltage supervisor, interval timer with watchdog function and a sophisticated on-chip clock generation with integrated RC-, 32-kHz crystal- and 4-MHz crystal-oscillators.

## MARC4 Architecture

### General Description

The MARC4 microcontroller consists of an advanced stack-based, 4-bit CPU core and on-chip peripherals. The CPU is based on the Harvard architecture with physically separated program memory (ROM) and data memory (RAM). Three independent buses, the instruction bus, the memory bus and the I/O bus, are used for parallel communication between ROM, RAM and peripherals. This enhances program execution speed by allowing both instruction prefetching, and a simultaneous communication to the on-chip peripheral circuitry. The extremely powerful integrated interrupt controller with associated eight prioritized interrupt levels supports fast and efficient processing of hardware events. The MARC4 is designed for the high-level programming language qFORTH. The core includes both, an expression and a return stack. This architecture enables high-level language programming without any loss of efficiency or code density.

**Figure 3.** MARC4 Core

## Components of MARC4 Core

Figure 4. ROM Map

The core contains ROM, RAM, ALU, program counter, RAM address registers, instruction decoder and interrupt controller. The following sections describe each functional block in more detail:

### ROM

The program memory (ROM) is mask programmed with the customer application program during fabrication of the microcontroller. The 2 Kbyte ROM size is addressed by a 12-bit wide program counter. An additional 1-Kbyte of ROM exists which is reserved for quality control self-test software. The lowest user ROM address segment is taken up by a 512-byte Zero page which contains predefined start addresses for interrupt service routines and special subroutines accessible with single byte instructions (SCALL).

The corresponding memory map is shown in Figure 4. Look-up tables of constants can also be held in ROM and are accessed via the MARC4's built-in table instruction.

### RAM

The ATAR080-D contains 256 x 4-bit wide static random access memory (RAM) which is used for the expression stack. The return stack and data memory are used for variables and arrays. The RAM is addressed by any of the four 8-bit wide RAM address registers SP, RP, X and Y.

#### Expression Stack

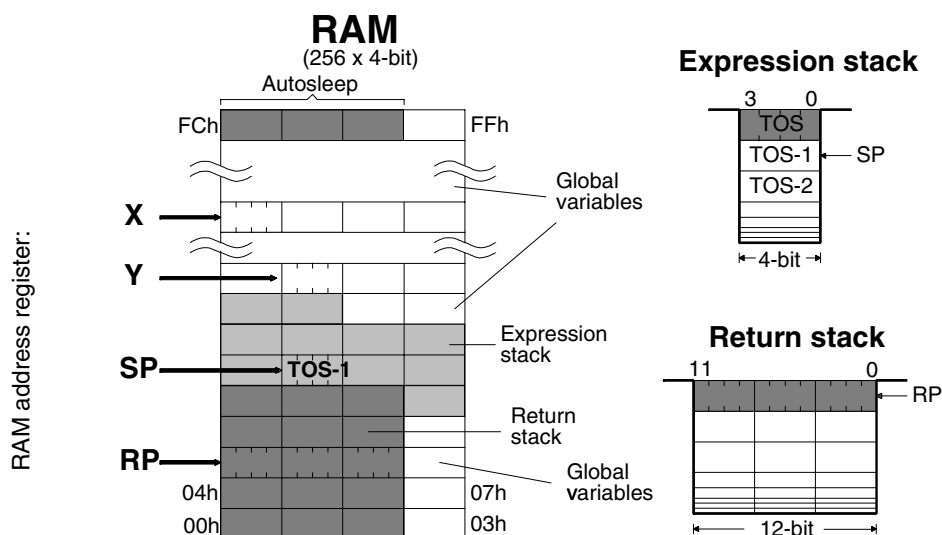

The 4-bit wide expression stack is addressed with the expression stack pointer (SP). All arithmetic, I/O and memory reference operations take their operands from, and return their results to the expression stack. The MARC4 performs the operations with the top of stack items (TOS and TOS-1). The TOS register contains the top element of the expression stack and works in the same way as an accumulator. This stack is also used for passing parameters between subroutines and as a scratch pad area for temporary storage of data.

#### Return Stack

The 12-bit wide return stack is addressed by the return stack pointer (RP). It is used for storing return addresses of subroutines, interrupt routines and for keeping loop index counts. The return stack can also be used as a temporary storage area.

The MARC4 instruction set supports the exchange of data between the top elements of the expression stack and the return stack. The two stacks within the RAM have a user definable location and maximum depth.

**Figure 5. RAM Map**

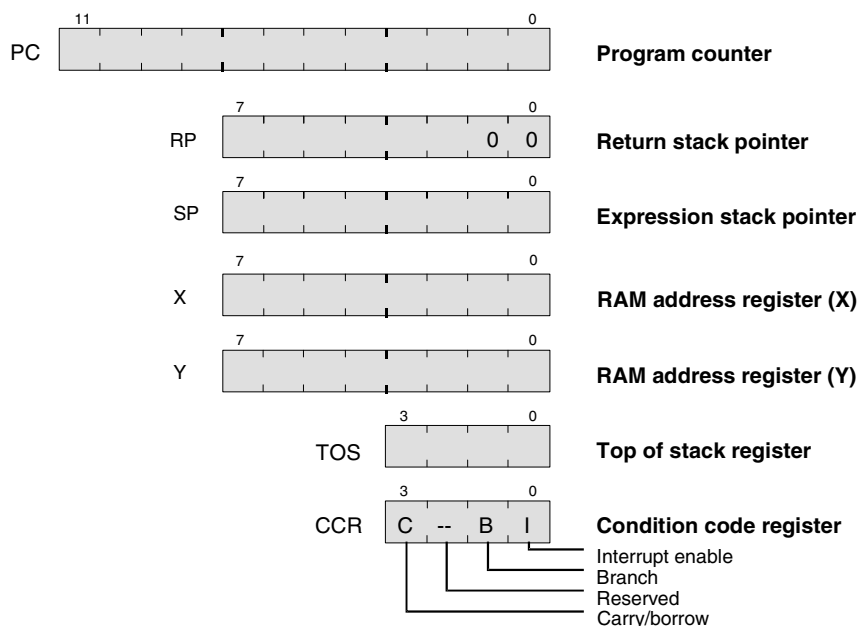

## Registers

The microcontroller has seven programmable registers and one condition code register (see Figure 6).

### Program Counter (PC)

The program counter is a 12-bit register which contains the address of the next instruction to be fetched from ROM. Instructions currently being executed are decoded in the instruction decoder to determine the internal micro-operations. For linear code (no calls or branches), the program counter is incremented with every instruction cycle. If a branch-, call-, return-instruction or an interrupt is executed, the program counter is loaded with a new address. The program counter is also used with the TABLE instruction to fetch 8-bit wide ROM constants.

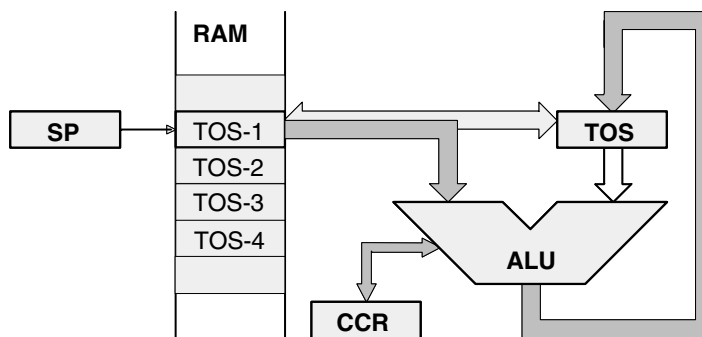

**Figure 6. Programming Model**

<i>RAM Address Registers</i>	The RAM is addressed with the four 8-bit wide RAM address registers: SP, RP, X and Y. These registers allow access to any of the 256 RAM nibbles.
<i>Expression Stack Pointer (SP)</i>	The stack pointer contains the address of the next-to-top 4-bit item (TOS-1) of the expression stack. The pointer is automatically pre-incremented if a nibble is moved onto the stack or post-decremented if a nibble is removed from the stack. Every post-decrement operation moves the item (TOS-1) to the TOS register before the SP is decremented. After a reset, the stack pointer has to be initialized with >SP S0 to allocate the start address of the expression stack area.
<i>Return Stack Pointer (RP)</i>	The return stack pointer points to the top element of the 12-bit wide return stack. The pointer automatically pre-increments if an element is moved onto the stack, or it post-decrements if an element is removed from the stack. The return stack pointer increments and decrements in steps of 4. This means that every time a 12-bit element is stacked, a 4-bit RAM location is left unwritten. This location is used by the qFORTH compiler to allocate 4-bit variables. After a reset the return stack pointer has to be initialized via >RP FCh.
<i>RAM Address Registers (X and Y)</i>	The X and Y registers are used to address any 4-bit item in RAM. A fetch operation moves the addressed nibble onto the TOS. A store operation moves the TOS to the addressed RAM location. By using either the pre-increment or post-decrement addressing modes arrays in the RAM can be compared, filled or moved.
<i>Top Of Stack (TOS)</i>	The top of stack register is the accumulator of the MARC4. All arithmetic/logic, memory reference and I/O operations use this register. The TOS register receives data from the ALU, ROM, RAM or I/O bus.
<i>Condition Code Register (CCR)</i>	The 4-bit wide condition code register contains the branch, the carry and the interrupt enable flag. These bits indicate the current state of the CPU. The CCR flags are set or reset by ALU operations. The instructions SET_BCF, TOG_BF, CCR! and DI allow direct manipulation of the condition code register.
<i>Carry/Borrow (C)</i>	The carry/borrow flag indicates that the borrowing or carrying out of the Arithmetic Logic Unit (ALU) occurred during the last arithmetic operation. During shift and rotate operations, this bit is used as a fifth bit. Boolean operations have no effect on the C-flag.
<i>Branch (B)</i>	The branch flag controls the conditional program branching. Should the branch flag have been set by a previous instruction a conditional branch will cause a jump. This flag is affected by arithmetic, logic, shift, and rotate operations.
<i>Interrupt Enable (I)</i>	The interrupt enable flag globally enables or disables the triggering of all interrupt routines with the exception of the non-maskable reset. After a reset or on executing the DI instruction, the interrupt enable flag is reset thus disabling all interrupts. The core will not accept any further interrupt requests until the interrupt enable flag has been set again by either executing an EI or SLEEP instruction.

## ALU

**Figure 7. ALU Zero-address Operations**

The 4-bit ALU performs all the arithmetic, logical, shift and rotate operations with the top two elements of the expression stack (TOS and TOS-1) and returns the result to the TOS. The ALU operations affect the carry/borrow and branch flag in the condition code register (CCR).

## I/O Bus

The I/O ports and the registers of the peripheral modules are I/O mapped. All communication between the core and the on-chip peripherals take place via the I/O bus and the associated I/O control. With the MARC4 IN and OUT instructions, the I/O bus allows a direct read or write access to one of the 16 primary I/O addresses. More about the I/O access to the on-chip peripherals is described in the section “Peripheral Modules”. The I/O bus is internal and is not accessible by the customer on the final microcontroller device, but it is used as the interface for the MARC4 emulation (see section “Emulation”).

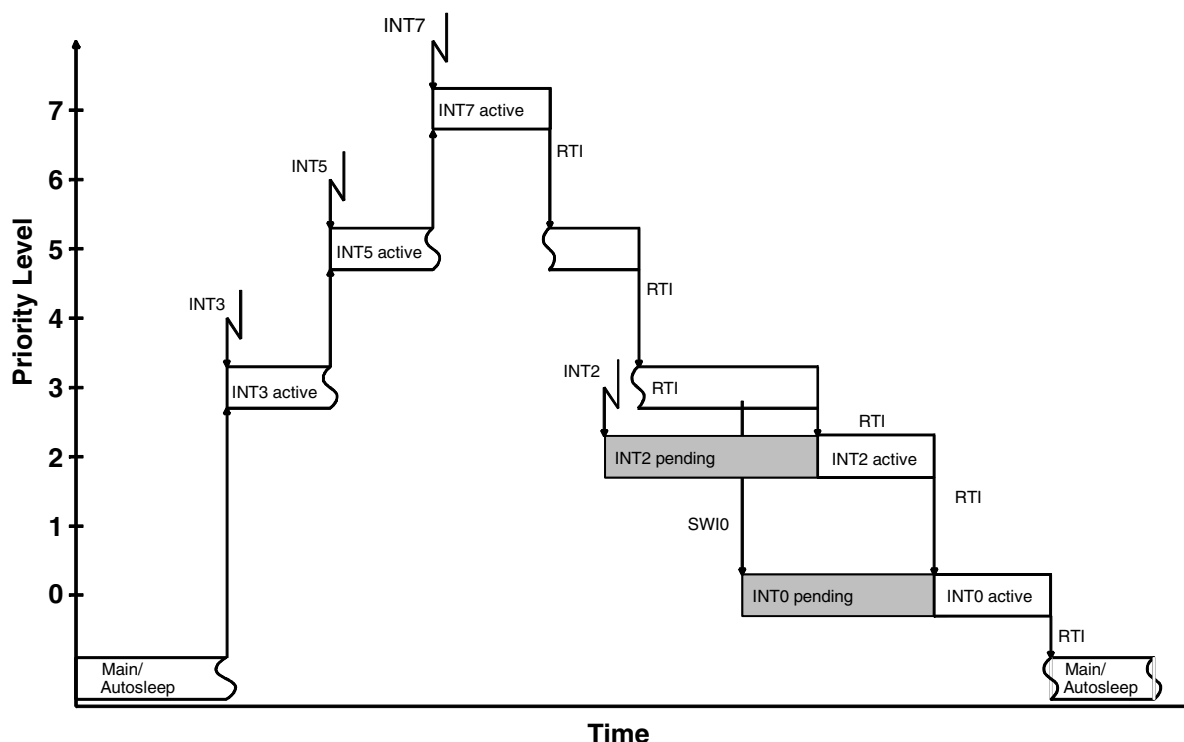

## Instruction Set

The MARC4 instruction set is optimized for the high level programming language qFORTH. Many MARC4 instructions are qFORTH words. This enables the compiler to generate a fast and compact program code. The CPU has an instruction pipeline allowing the controller to prefetch an instruction from ROM at the same time as the present instruction is being executed. The MARC4 is a zero address machine, the instructions containing only the operation to be performed and no source or destination address fields. The operations are implicitly performed on the data placed on the stack. There are one and two byte instructions which are executed within 1 to 4 machine cycles. A MARC4 machine cycle is made up of two system clock cycles (SYSCL). Most of the instructions are only one byte long and are executed in a single machine cycle. For more information refer to the “MARC4 Programmer's Guide”.

## Interrupt Structure

The MARC4 can handle interrupts with eight different priority levels. They can be generated from the internal and external interrupt sources or by a software interrupt from the CPU itself. Each interrupt level has a hard-wired priority and an associated vector for the service routine in the ROM (see Table 1 on page 9). The programmer can postpone the processing of interrupts by resetting the interrupt enable flag (I) in the CCR. An interrupt occurrence will still be registered, but the interrupt routine only starts after the I flag is set. All interrupts can be masked, and the priority individually software configured by programming the appropriate control register of the interrupting module (see section “Peripheral Modules”).

**Figure 8.** Interrupt Handling

### Interrupt Processing

In order to be able to process the eight interrupt levels, the MARC4 contains an interrupt controller with two 8-bit wide “interrupt pending” and “interrupt active” registers. The interrupt controller samples all interrupt requests during every non-I/O instruction cycle and latches these in the interrupt pending register. If no higher priority interrupt is present in the interrupt active register, it signals the CPU to interrupt the current program execution. If the interrupt enable bit is set, the processor enters an interrupt acknowledge cycle. During this cycle a short call (SCALL) instruction to the service routine is executed and the current PC is saved on the return stack. An interrupt service routine is completed with the RTI instruction. This instruction resets the corresponding bits in the interrupt pending/active register and fetches the return address from the return stack to the program counter. When the interrupt enable flag is reset (triggering of interrupt routines are disabled), the execution of new interrupt service routines is inhibited but not the logging of the interrupt requests in the interrupt pending register. The execution of the interrupt is delayed until the interrupt enable flag is set again. Note that interrupts are only lost if an interrupt request occurs while the corresponding bit in the pending register is still set (i.e., the interrupt service routine is not yet finished).

### Interrupt Latency

The interrupt latency is the time from the occurrence of the interrupt to the interrupt service routine being activated. This is extremely short (taking between 3 to 5 machine cycles depending on the state of the core).

**Table 1.** Interrupt Priority Table

Interrupt	Priority	ROM Address	Interrupt Opcode	Function
INT0	lowest	040h	C8h (SCALL 040h)	Software interrupt (SWI0)
INT1	I	080h	D0h (SCALL 080h)	External hardware interrupt, any edge at BP52 or BP53
INT2	I	0C0h	D8h (SCALL 0C0h)	Timer 1 interrupt
INT3	I	100h	E8h (SCALL 100h)	SSI interrupt or external hardware interrupt at BP40 or BP43
INT4	I	140h	E8h (SCALL 140h)	Timer 2 interrupt
INT5	I	180h	F0h (SCALL 180h)	Software interrupt (SWI5)
INT6	↓	1C0h	F8h (SCALL 1C0h)	External hardware interrupt, at any edge at BP50 or BP51
INT7	highest	1E0h	FCh (SCALL 1E0h)	Voltage monitor (VM) interrupt

**Table 2.** Hardware Interrupts

Interrupt	Interrupt Mask		Interrupt Source
	Register	Bit	
INT1	P5CR	P52M1, P52M2 P53M1, P53M2	Any edge at BP52 Any edge at BP53
INT2	T1M	T1IM	Timer 1
INT3	SISC	SIM	SSI buffer full/empty or BP40/BP43 interrupt
INT4	T2CM	T2IM	Timer 2 compare match/overflow
INT6	P5CR	P50M1, P50M2 P51M1, P51M2	Any edge at BP50 Any edge at BP51
INT7	VCM	VIM	External/internal voltage monitoring

#### Software Interrupts

The programmer can generate interrupts by using the software interrupt instruction (SWI), which is supported in qFORTH by predefined macros named SWI0...SWI7. The software triggered interrupt operates exactly like any hardware triggered interrupt. The SWI instruction takes the top two elements from the expression stack and writes the corresponding bits via the I/O bus to the interrupt pending register. Therefore, by using the SWI instruction, interrupts can be re-prioritized or lower priority processes scheduled for later execution.

#### Hardware Interrupts

In the ATAR080-D, there are eleven hardware interrupt sources with seven different levels. Each source can be masked individually by mask bits in the corresponding control registers. An overview of the possible hardware configurations is shown in Table 2.

## Master Reset

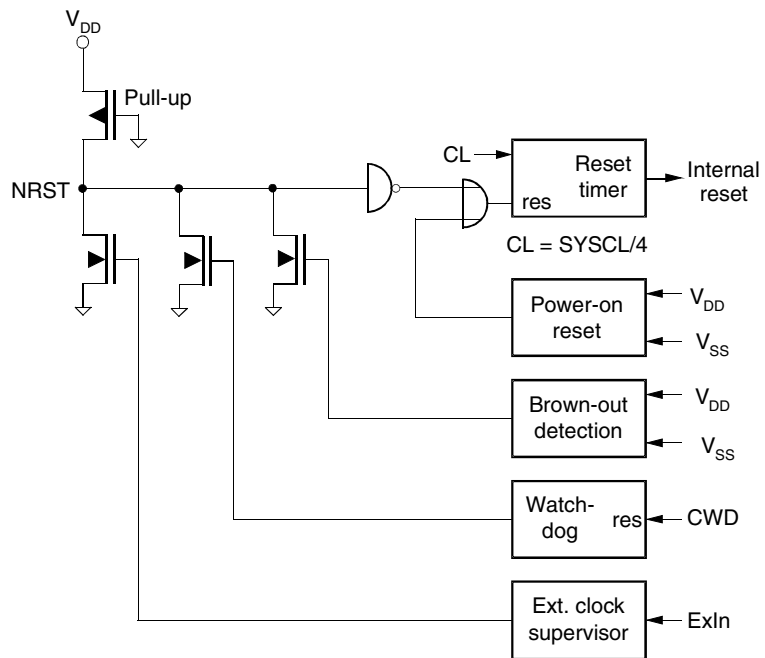

The master reset forces the CPU into a well-defined condition. It is unmaskable and is activated independent of the current program state. It can be triggered by either initial supply power-up, a short collapse of the power supply, the brown-out detection circuitry, a watchdog time-out, or an external input clock supervisor stage (see Figure 9).

A master reset activation will reset the interrupt enable flag, the interrupt pending register and the interrupt active register. During the power-on reset phase, the I/O bus control signals are set to reset mode thereby initializing all on-chip peripherals. All bi-directional ports are set to input mode.

**Attention:** During any reset phase, the BP20/NTE input is driven towards  $V_{DD}$  by an additional internal strong pull-up transistor. This pin must not be pulled down to  $V_{SS}$  during reset by any external circuitry representing a resistor of less than 150 k $\Omega$ .

Releasing the reset results in a short call instruction (opcode C1h) to the ROM address 008h. This activates the initialization routine \$RESET which in turn has to initialize all necessary RAM variables, stack pointers and peripheral configuration registers.

**Figure 9.** Reset Configuration

## Power-on Reset and Brown-out Detection

The ATAR080-D has a fully integrated power-on reset and brown-out detection circuitry. For reset generation no external components are needed.

These circuits ensure that the core is held in the reset state until the minimum operating supply voltage has been reached. A reset condition will also be generated should the supply voltage drop momentarily below the minimum operating level except when a power-down mode is activated (the core is in SLEEP mode and the peripheral clock is stopped). In this power-down mode the brown-out detection is disabled.

Two values for the brown-out voltage threshold are programmable via the BOT bit in the SC register.

**Figure 10. Brown-out Detection**

Note: BOT = 1, low brown-out voltage threshold. (1.65 V is the reset value).  
 BOT = 0, high brown-out voltage threshold (1.95 V).

A power-on reset pulse is generated by a  $V_{DD}$  rise across the default BOT voltage level (1.65 V). A brown-out reset pulse is generated when  $V_{DD}$  falls below the brown-out voltage threshold. Two values for the brown-out voltage threshold are programmable via the BOT bit in the SC register. When the controller runs in the upper supply voltage range with a high system clock frequency, the high threshold must be used. When it runs with a lower system clock frequency, the low threshold and a wider supply voltage range may be chosen. For further details, see the electrical specification and the SC register description for BOT programming.

### Watchdog Reset

The watchdog's function can be enabled at the WDC-register and triggers a reset with every watchdog counter overflow. To suppress the watchdog reset, the watchdog counter must be regularly reset by reading the watchdog register address (CWD). The CPU reacts in exactly the same manner as a reset stimulus from any of the above sources.

### External Clock Supervisor

The external input clock supervisor function can be enabled if the external input clock is selected within the CM- and SC registers of the clock module. The CPU reacts in exactly the same manner as a reset stimulus from any of the above sources.

### Voltage Monitor

The voltage monitor consists of a comparator with internal voltage reference. It is used to supervise the supply voltage or an external voltage at the VMI pin. The comparator for the supply voltage has three internal programmable thresholds: one lower threshold (2.15 V), one middle threshold (2.55 V) and one higher threshold (2.95 V). For external voltages at the VMI pin, the comparator threshold is set to  $V_{BG} = 1.25 \text{ V}$ . The VMS-bit indicates if the supervised voltage is below ( $VMS = 0$ ) or above ( $VMS = 1$ ) this threshold. An interrupt can be generated when the VMS-bit is set or reset to detect a rising or falling slope. A voltage monitor interrupt (INT7) is enabled when the interrupt mask bit (VIM) is reset in the VMC-register.

**Figure 11. Voltage Monitor**

### Voltage Monitor Control/ Status Register

Primary register address: 'F'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>VMC: Write</b>	<b>VM2</b>	<b>VM1</b>	<b>VM0</b>	<b>VIM</b>	<b>Reset value: 1111b</b>
<b>VMST: Read</b>	-	-	reserved	<b>VMS</b>	<b>Reset value: xx11b</b>

**VM2:** Voltage monitor Mode bit 2  
**VM1:** Voltage monitor Mode bit 1  
**VM0:** Voltage monitor Mode bit 0

**Table 3. Voltage Monitor Modes**

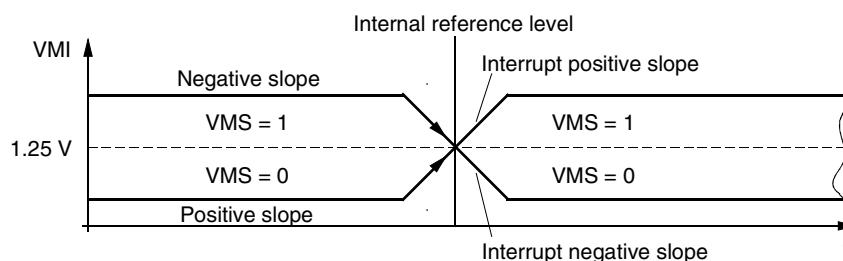

VM2	VM1	VM0	Function
1	1	1	Disable voltage monitor
1	1	0	External (VIM input), internal reference threshold (1.25 V), interrupt with negative slope
1	0	1	Not allowed
1	0	0	External (VMI input), internal reference threshold (1.25 V), interrupt with positive slope
0	1	1	Internal (supply voltage), high threshold (2.95 V), interrupt with negative slope
0	1	0	Internal (supply voltage), middle threshold (2.55 V), interrupt with negative slope
0	0	1	Internal (supply voltage), low threshold (2.15 V), interrupt with negative slope
0	0	0	Not allowed

**VIM Voltage Interrupt Mask bit**

- VIM = 0, voltage monitor interrupt is enabled
- VIM = 1, voltage monitor interrupt is disabled

**VMS Voltage Monitor Status bit**

- VMS = 0, the voltage at the comparator input is below  $V_{ref}$
- VMS = 1, the voltage at the comparator input is above  $V_{ref}$

## Clock Generation

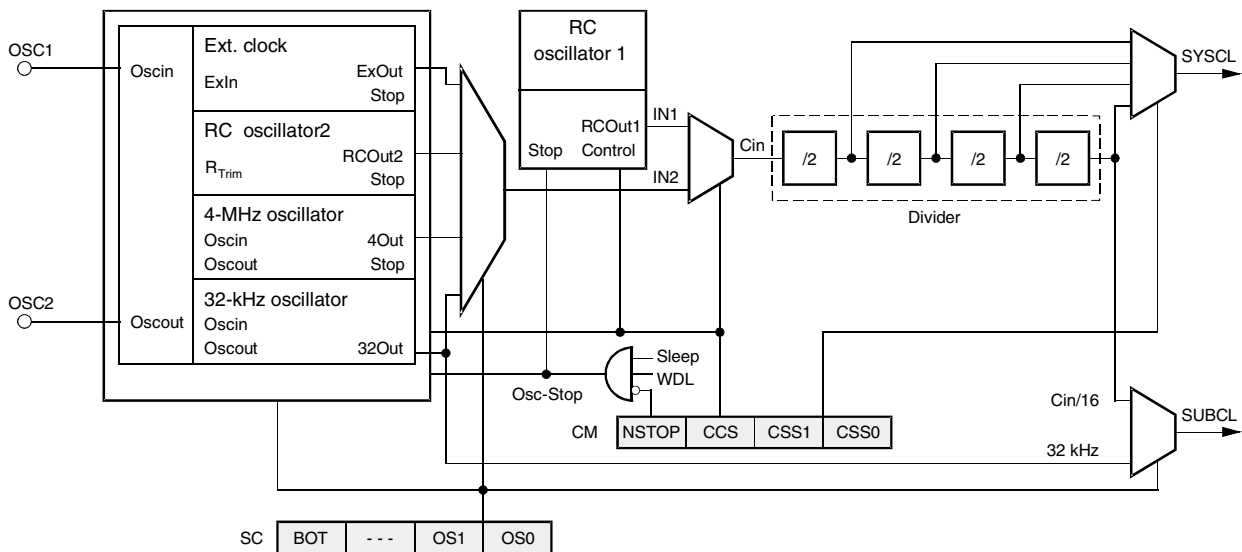

### Clock Module

The ATAR080-D contains a clock module with 4 different internal oscillator types: two RC-oscillators, one 4-MHz crystal oscillator and one 32-kHz crystal oscillator. The pins OSC1 and OSC2 are the interface to connect a crystal either to the 4-MHz, or to the 32-kHz crystal oscillator. OSC1 can be used as input for external clocks or to connect an external trimming resistor for the RC-oscillator 2. All necessary circuitry, except the crystal and the trimming resistor, is integrated on-chip. One of these oscillator types or an external input clock can be selected to generate the system clock (SYSCL).

In applications that do not require exact timing, it is possible to use the fully integrated RC-oscillator 1 without any external components. The RC-oscillator 1 center frequency tolerance is better than  $\pm 60\%$ . The RC-oscillator 2 is a trimmable oscillator whereby the oscillator frequency can be trimmed with an external resistor attached between OSC1 and GND. In this configuration, the RC-oscillator 2 frequency can be maintained stable to within a tolerance of  $\pm 15\%$  over the full operating temperature and voltage range.

The clock module is programmable via software with the clock management register (CM) and the system configuration register (SC). The required oscillator configuration can be selected with the OS1-bit and the OS0-bit in the SC register. A programmable 4-bit divider stage allows the adjustment of the system clock speed. A special feature of the clock management is that an external oscillator may be used and switched on and off via a port pin for the power-down mode. Before the external clock is switched off, the internal RC-oscillator 1 must be selected with the CCS-bit and then the SLEEP mode may be activated. In this state an interrupt can wake up the controller with the RC-oscillator, and the external oscillator can be activated and selected by software. A synchronization stage avoids clock periods that are too short if the clock source or the clock speed is changed. If an external input clock is selected, a supervisor circuit monitors the external input and generates a hardware reset if the external clock source fails or drops below 500 kHz for more than 1 ms.

**Figure 14. Clock Module**

**Table 4. Clock Modes**

Mode	OS1	OS0	Clock Source for SYSCL		Clock Source for SUBCL
			CCS = 1	CCS = 0	
1	1	1	RC-oscillator 1 (intern)	External input clock	$C_{in}/16$
2	0	1	RC-oscillator 1 (intern)	RC-oscillator 2 with external trimming resistor	$C_{in}/16$
3	1	0	RC-oscillator 1 (intern)	4-MHz oscillator	$C_{in}/16$
4	0	0	RC-oscillator 1 (intern)	32-kHz oscillator	32 kHz

The clock module generates two output clocks. One is the system clock (SYSCL) and the other the periphery (SUBCL). The SYSCL can supply the core and the peripherals and the SUBCL can supply only the peripherals with clocks. The modes for clock sources are programmable with the OS1-bit and OS0-bit in the SC register and the CCS-bit in the CM-register.

## Oscillator Circuits and External Clock Input Stage

The ATAR080-D consists of four different internal oscillators: two RC-oscillators, one 4-MHz crystal oscillator, one 32-kHz crystal oscillator and one external clock input stage.

### RC-oscillator 1 Fully Integrated

For timing insensitive applications, it is possible to use the fully integrated RC-oscillator 1. It operates without any external components and saves additional costs. The RC-oscillator 1 center frequency tolerance is better than  $\pm 60\%$  over the full temperature and voltage range. The basic center frequency of the RC-oscillator 1 is  $f_0 \approx 3.8\text{-MHz}$ . The RC-oscillator 1 is selected by default after power-on reset.

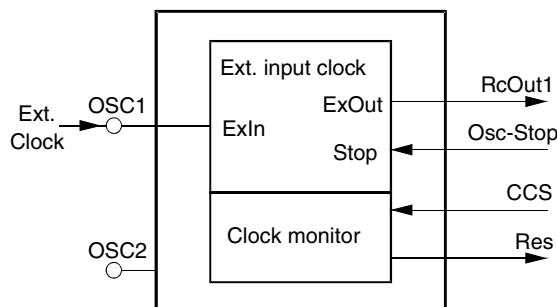

**Figure 15.** RC-oscillator 1

### External Input Clock

The OSC1 or OSC2 (mask option) can be driven by an external clock source provided it meets the specified duty cycle, rise and fall times and input levels. Additionally, the external clock stage contains a supervisory circuit for the input clock. The supervisor function is controlled via the OS1, OS0-bit in the SC register and the CCS-bit in the CM-register. If the external input clock fails and CCS = 0 is set in the CM-register, the supervisory circuit generates a hardware reset. The input clock has failed if the frequency is less than 500 kHz for more than 1 ms.

**Figure 16.** External Input Clock

**Table 5.** Supervisor Function Control Bits

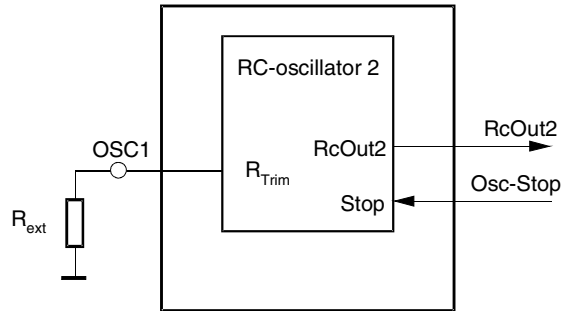

OS1	OS0	CCS	Supervisor Reset Output (Res)
1	1	0	Enable
1	1	1	Disable
x	0	x	Disable

### RC-oscillator 2 with External Trimming Resistor

The RC-oscillator 2 is a high resolution trimmable oscillator whereby the oscillator frequency can be trimmed with an external resistor between OSC1 and VSS. In this configuration, the RC-oscillator 2 frequency can be maintained stable to within a tolerance of  $\pm 15\%$  over the full operating temperature and voltage range from  $V_{DD} = 2.0\text{ V}$  to  $6.5\text{ V}$ .

For example: An output frequency at the RC-oscillator 2 of  $1.6\text{ MHz}$ , can be obtained by connecting a resistor  $R_{ext} = 47\text{ k}\Omega$  (see Figure 17).

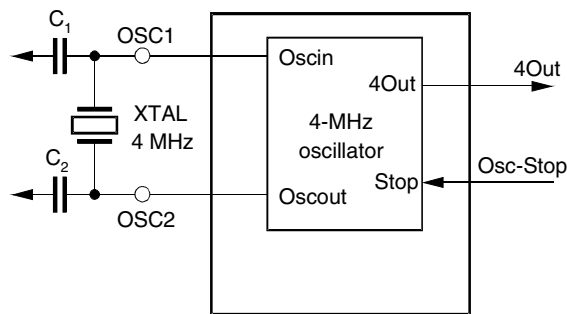

**Figure 17.** RC-oscillator 2

### 4-MHz Oscillator

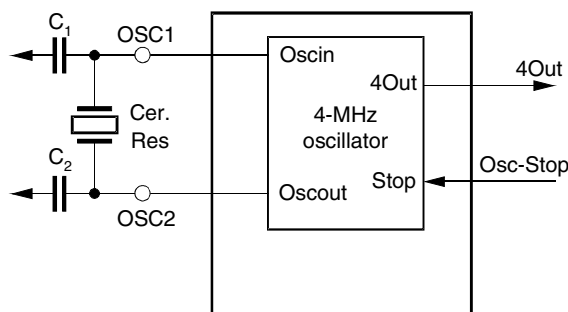

The ATAR080-D 4-MHz oscillator options need a crystal or ceramic resonator connected to the OSC1 and OSC2 pins to establish oscillation. All the necessary oscillator circuitry is integrated, with the exception of the actual crystal, resonator and the capacitors  $C_1$  and  $C_2$ .

**Figure 18.** 4-MHz Crystal Oscillator

**Note:** Both, the 4-MHz and the 32-kHz crystal oscillator, use an integrated 14 stage divider circuit to stabilize oscillation before the oscillator output is used as system clock. This results in an additional delay of about  $4\text{ ms}$  for the 4-MHz crystal and about  $500\text{ ms}$  for the 32-kHz crystal.

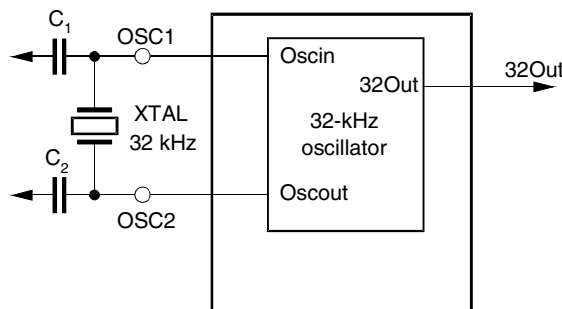

**Figure 19. Ceramic Resonator**

**Note:** Both, the 4-MHz and the 32-kHz crystal oscillator, use an integrated 14 stage divider circuit to stabilize oscillation before the oscillator output is used as system clock. This results in an additional delay of about 4 ms for the 4-MHz crystal and about 500 ms for the 32-kHz crystal.

### 32-kHz Oscillator

Some applications require long-term time keeping or low resolution timing. In this case, an on-chip, low power 32-kHz crystal oscillator can be used to generate both the SUBCL and the SYSCL. In this mode, power consumption is greatly reduced. The 32-kHz crystal oscillator can not be stopped while the power-down mode is in operation.

**Figure 20. 32-kHz Crystal Oscillator**

**Note:** Both, the 4-MHz and the 32-kHz crystal oscillator, use an integrated 14 stage divider circuit to stabilize oscillation before the oscillator output is used as system clock. This results in an additional delay of about 4 ms for the 4-MHz crystal and about 500 ms for the 32-kHz crystal.

### Clock Management

The clock management register controls the system clock divider and synchronization stage. Writing to this register triggers the synchronization cycle.

## Clock Management Register (CM)

Auxiliary register address: '3'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>CM</b>	<b>NSTOP</b>	<b>CCS</b>	<b>CSS1</b>	<b>CSS0</b>	<b>Reset value: 1111b</b>

<b>NSTOP</b>	<b>Not STOP</b> peripheral clock NSTOP = 0, stops the peripheral clock while the core is in SLEEP mode NSTOP = 1, enables the peripheral clock while the core is in SLEEP mode
<b>CCS</b>	<b>Core Clock Select</b> CCS = 1, the internal RC-oscillator 1 generates SYSCL CCS = 0, the 4-Mhz crystal oscillator, the 32-kHz crystal oscillator, an external clock source or the RC-oscillator 2 with the external resistor at OSC1 generates SYSCL dependent on the setting of OS0 and OS1 in the system configuration register
<b>CSS1</b>	<b>Core Speed Select 1</b>

1	1	1	$C_{in}/16$	RC-oscillator 1 and external input clock
2	0	1	$C_{in}/16$	RC-oscillator 1 and RC-oscillator 2
3	1	0	$C_{in}/16$	RC-oscillator 1 and 4-MHz crystal oscillator
4	0	0	32 kHz	RC-oscillator 1 and 32-kHz crystal oscillator

Note: If the bit CCS = 0 in the CM-register the RC-oscillator 1 always stops.

## Power-down Modes

The sleep mode is a shut-down condition which is used to reduce the average system power consumption in applications where the microcontroller is not fully utilized. In this mode, the system clock is stopped. The sleep mode is entered via the SLEEP instruction. This instruction sets the interrupt enable bit (I) in the condition code register to enable all interrupts and stops the core. During the sleep mode the peripheral modules remain active and are able to generate interrupts. The microcontroller exits the sleep mode by carrying out any interrupt or a reset.

The sleep mode can only be maintained while none of the interrupt pending or active register bits are set. The application of the \$AUTOSLEEP routine ensures the correct function of the sleep mode. For standard applications use the \$AUTOSLEEP routine to enter the power-down mode. Using the SLEEP instruction instead of the \$AUTOSLEEP following an I/O instruction requires the insertion of 3 non-I/O instruction cycles (for example NOP NOP NOP) between the IN or OUT command and the SLEEP command.

The total power consumption is directly proportional to the active time of the microcontroller. For a rough estimation of the expected average system current consumption, the following formula should be used:

$$I_{\text{total}}(V_{\text{DD}}, f_{\text{syscl}}) = I_{\text{Sleep}} + \left( I_{\text{DD}} \times \frac{t_{\text{active}}}{t_{\text{total}}} \right)$$

$I_{\text{DD}}$  depends on  $V_{\text{DD}}$  and  $f_{\text{syscl}}$ .

The ATAR080-D has various power-down modes. During the sleep mode the clock for the MARC4 core is stopped. With the NSTOP-bit in the clock management register (CM), it is programmable if the clock for the on-chip peripherals is active or stopped during the sleep mode. If the clock for the core and the peripherals is stopped the selected oscillator is switched off. An exception is the 32-kHz oscillator, if it is selected it runs continuously independent of the NSTOP-bit. If the oscillator is stopped or the 32-kHz oscillator is selected, power consumption is extremely low.

**Table 8.** Power-down Modes

Mode	CPU Core	Osc-Stop <sup>(1)</sup>	Brown-out Function	RC-oscillator 1 RC-oscillator 2 4-MHz Oscillator	32-kHz Oscillator	External Input Clock
Active	RUN	NO	Active	RUN	RUN	YES
Power-down	SLEEP	NO	Active	RUN	RUN	YES
SLEEP	SLEEP	YES	STOP	STOP	RUN	STOP

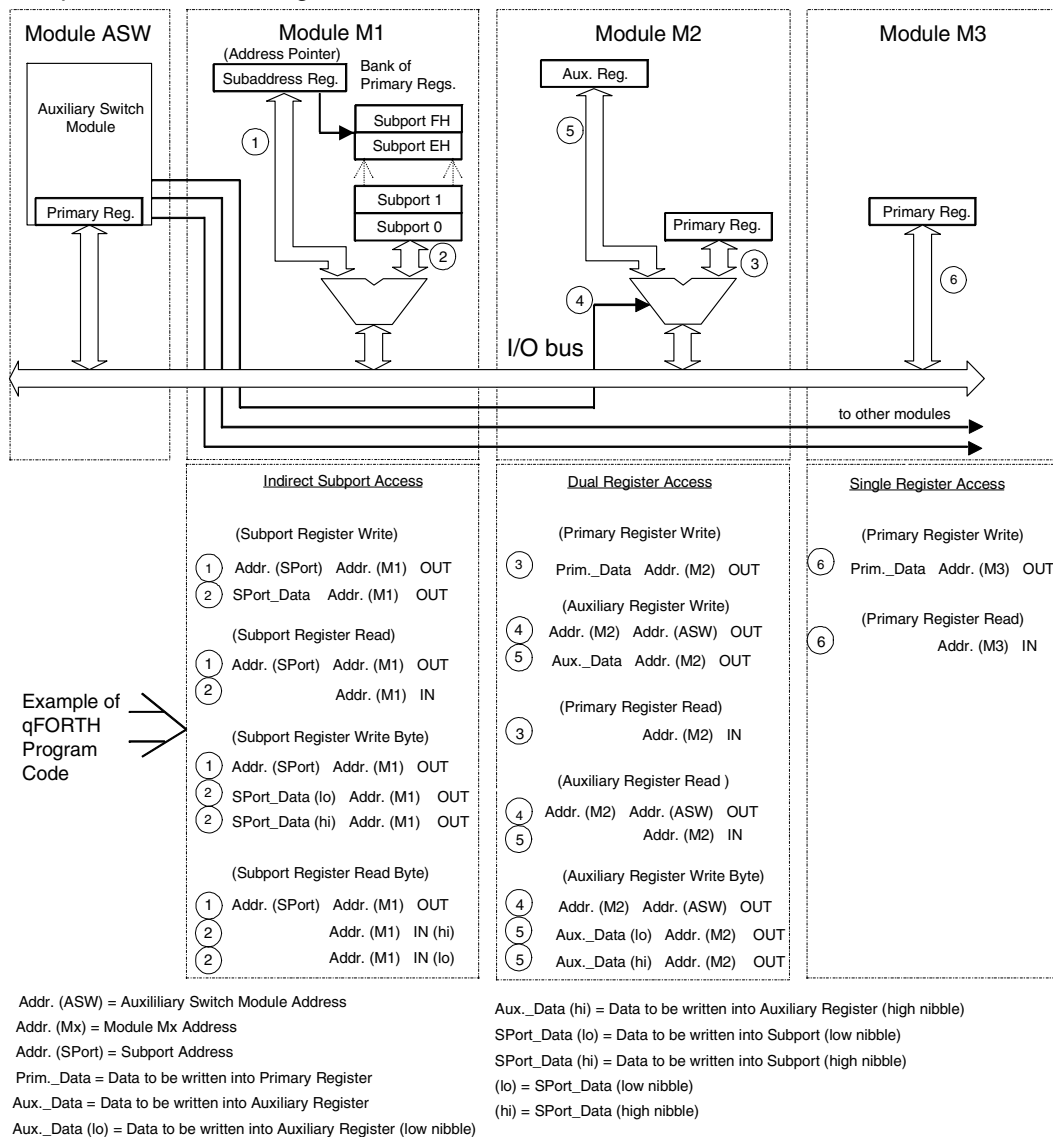

Note: 1. Osc-Stop = SLEEP and NSTOP and WDL

## Peripheral Modules

## Addressing Peripherals

Accessing the peripheral modules takes place via the I/O bus (see Figure 21). The IN or OUT instructions allow direct addressing of up to 16 I/O modules. A dual register addressing scheme has been adopted to enable direct addressing of the primary register. To address the auxiliary register, the access must be switched with an auxiliary switching module. Thus, a single IN (or OUT) to the module address will read (or write into) the module's primary register. Accessing the auxiliary register is performed with the same instruction preceded by writing the module address into the auxiliary switching module. Byte wide registers are accessed by multiple IN (or OUT) instructions. For more complex peripheral modules, with a larger number of registers, extended addressing is used. In this case, a bank of up to 16 subport registers are indirectly addressed with the subport address. The first OUT-instruction writes the subport address to the sub-address register, the second IN or OUT instruction reads data from or writes data to the addressed subport.

**Figure 21. Example of I/O Addressing**

## Bi-directional Ports

All ports (2, 4 and 5) are 4 bits wide. All ports may be used for data input or output. All ports are equipped with Schmitt trigger inputs and a variety of mask options for open-drain, open-source, full-complementary outputs, pull-up and pull-down transistors. All Port Data Registers (PxDAT) are I/O mapped to the primary address register of the respective port address and the Port Control Register (PxCR), to the corresponding auxiliary register.

There are three different directional ports available:

Port 2 - 4-bit wide bitwise-programmable I/O port.

Port 5 - 4-bit wide bitwise-programmable bi-directional port with optional static pull-ups and programmable interrupt logic.

Port 4 - 4-bit wide bitwise-programmable bi-directional port also provides the I/O interface to Timer 2, SSI, voltage monitor input and external interrupt input.

### Bi-directional Port 2

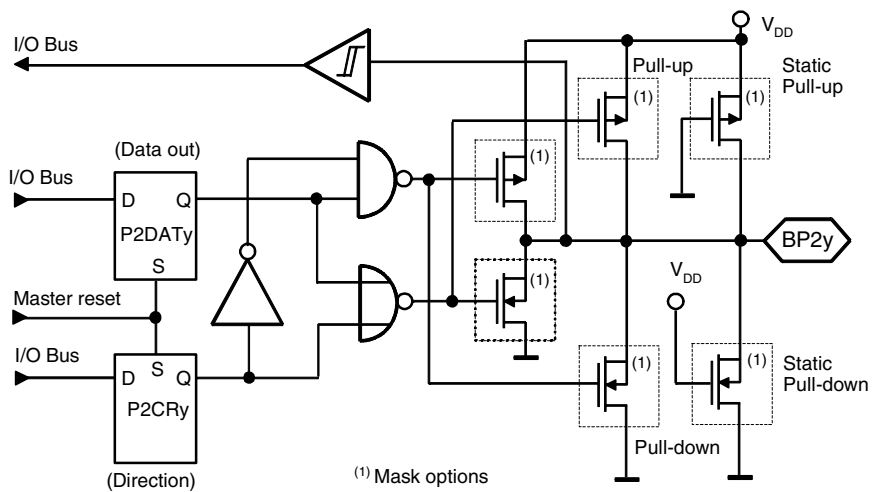

This, and all other bi-directional ports include a bitwise-programmable Control Register (P2CR), which enables the individual programming of each port bit as input or output. It also opens up the possibility of reading the pin condition when in output mode. This is a useful feature for self-testing and for serial bus applications.

Port 2 however, has an increased drive capability and an additional low resistance pull-up/-down transistor mask option.

Care should be taken connecting external components to BP20/NTE. During any reset phase, the BP20/NTE input is driven towards  $V_{DD}$  by an additional internal strong pull-up transistor. This pin must not be pulled down (active or passive) to  $V_{SS}$  during reset by any external circuitry representing a resistor of less than 150 k $\Omega$ . This prevents the circuit from unintended switching to test mode enable through the application circuitry at Pin BP20/NTE. Resistors less than 150 k $\Omega$  might lead to an undefined state of the internal test logic thus disabling the application firmware.

To avoid any conflict with the optional internal pull-down transistors, BP20 handles the pull-down options in a different way than all other ports. BP20 is the only port that switches off the pull-down transistors during reset.

**Figure 22.** Bi-directional Port 2

## Port 2 Data Register (P2DAT)

Primary register address: '2'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
P2DAT	P2DAT3	P2DAT2	P2DAT1	P2DAT0	Reset value: 1111b

Bit 3 = MSB, Bit 0 = LSB

## Port 2 Control Register (P2CR)

Auxiliary register address: '2'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
P2CR	P2CR3	P2CR2	P2CR1	P2CR0	Reset value: 1111b

Value 1111b means all pins in input mode

x x x 0	BP20 in output mode
x x 1 x	BP21 in input mode
x x 0 x	BP21 in output mode
x 1 x x	BP22 in input mode
x 0 x x	BP22 in output mode
1 x x x	BP23 in input mode
0 x x x	BP23 in output mode

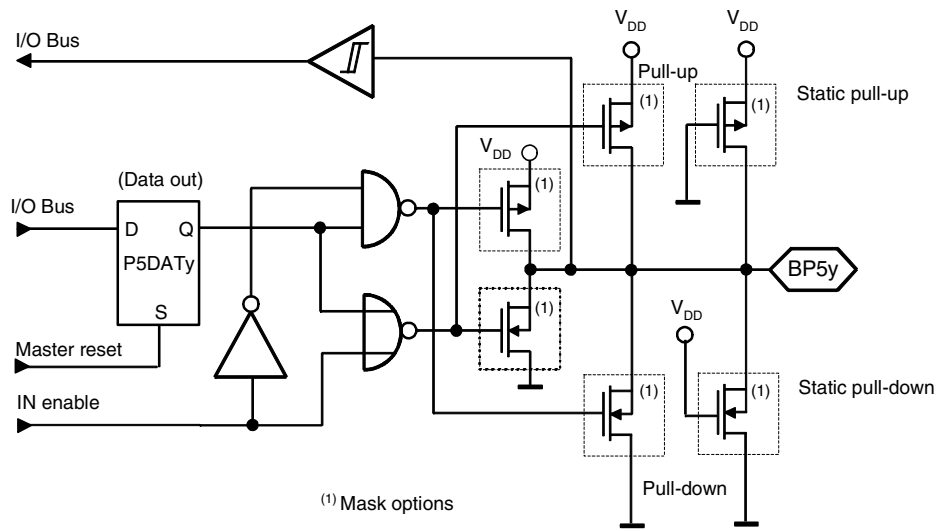

## Bi-directional Port 5

This, and all other bi-directional ports include a bitwise programmable Control Register (P5CR), which allows individual programming of each port bit as input or output. It also opens up the possibility of reading the pin condition when in output mode. This is a useful feature for self testing and for serial bus applications.

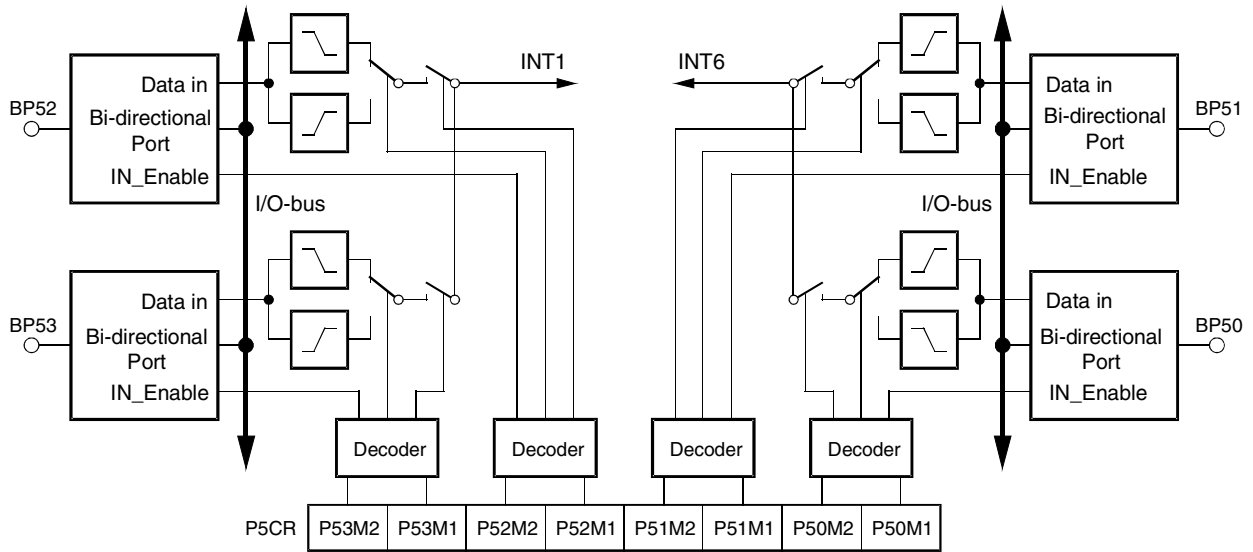

The port pins can also be used as external interrupt inputs (see Figure 23 on page 24 and Figure 24 on page 24). The interrupts (INT1 and INT6) can be masked or independently configured to trigger on either edge. The interrupt configuration and port direction is controlled by the Port 5 Control Register (P5CR). An additional low resistance pull-up/-down transistor mask option provides an internal bus pull-up for serial bus applications.

The Port 5 Data Register (P5DAT) is I/O mapped to the primary address register of address '5'h and the Port 5 Control Register (P5CR) to the corresponding auxiliary register. The P5CR is a byte-wide register and is configured by writing first the low nibble then the high nibble (see section "Addressing Peripherals").

## Bi-directional Port 4

The bi-directional Port 4 is both a bitwise configurable I/O port and provides the external pins for the Timer 2, SSI and the voltage monitor input (VMI). As a normal port, it performs in exactly the same way as bi-directional Port 2 (see Figure 22 on page 22). Two additional multiplexes allow data and port direction control to be passed over to other internal modules (Timer 2, VM or SSI). The I/O-pins for the SC and SD lines have an additional mode to generate an SSI-interrupt.

All four Port 4 pins can be individually switched by the P4CR-register. Figure 25 on page 26 shows the internal interfaces to bi-directional Port 4.

## Universal Timer/Counter/Communication Module (UTCM)

The Universal Timer/Counter/Communication Module (UTCM) consists of Timer 1, Timer 2 and a Synchronous Serial Interface (SSI).

- Timer 1 is an interval timer that can be used to generate periodical interrupts and as prescaler for Timer 2, the serial interface and the watchdog function.
- Timer 2 is an 8/12-bit timer with an external clock input (T2I) and an output (T2O).
- The SSI operates as a two-wire serial interface or as a shift register for modulation. The modulator units work together with the timers and shift the data bits out of the shift register.

There is a multitude of modes in which the timers and the serial interface can work together.

**Figure 26.** UTCM Block Diagram

### Timer 1

Timer 1 is an interval timer which can be used to generate periodic interrupts and as prescaler for Timer 2, Timer 3, the serial interface and the watchdog function.

Timer 1 consists of a programmable 14-stage divider that is driven by either SUBCL or SYSCL. The timer output signal can be used as a prescaler clock or as SUBCL and as a source for the Timer 1 interrupt. Because of other system requirements, Timer 1 output T1OUT is synchronized with SYSCL. Therefore, in the power-down mode SLEEP (CPU core →sleep and OSC-Stop →yes) the output T1OUT is stopped (T1OUT = 0). Nevertheless, Timer 1 can be active in SLEEP and generate Timer 1 interrupts. The interrupt is maskable via the T1IM bit and the SUBCL can be bypassed via the T1BP bit of the T1C2 register. The time interval for the timer output can be programmed via the Timer 1 control register T1C1.

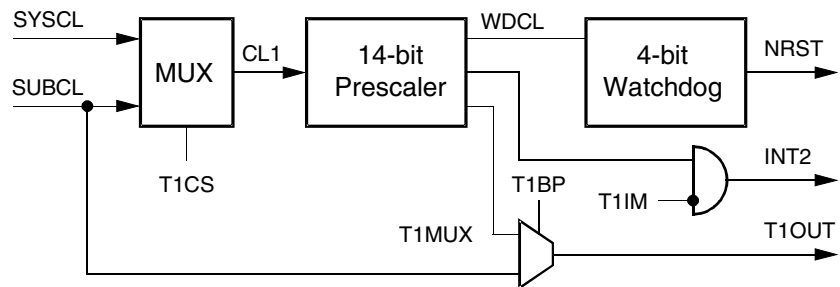

This timer starts running automatically after any power-on reset! If the watchdog function is not activated, the timer can be restarted by writing into the T1C1 register with T1RM = 1.

Timer 1 can also be used as a watchdog timer to prevent a system from stalling. The watchdog timer is a 3-bit counter that is supplied by a separate output of Timer 1. It generates a system reset when the 3-bit counter overflows. To avoid this, the 3-bit counter must be reset before it overflows. The application software has to accomplish this by reading the CWD register.

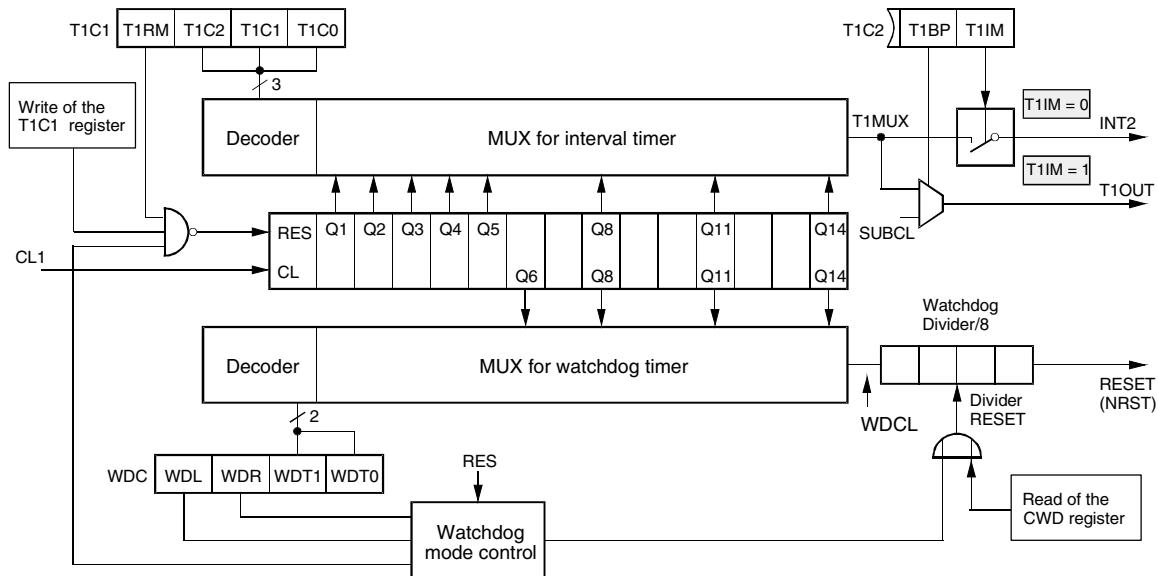

After power-on reset the watchdog must be activated by software in the \$RESET initialization routine. There are two watchdog modes, in one mode the watchdog can be switched on and off by software, in the other mode the watchdog is active and locked. This mode can only be stopped by carrying out a system reset.

The watchdog timer operation mode and the time interval for the watchdog reset can be programmed via the watchdog control register (WDC).

**Figure 27. Timer 1 Module**

**Figure 28. Timer 1 and Watchdog**

**Timer 1 Control Register 1  
(T1C1)**

Address: '7'hex - Subaddress: '8'hex

	Bit 3 <sup>(1)</sup>	Bit 2	Bit 1	Bit 0	
<b>T1C1</b>	<b>T1RM</b>	<b>T1C2</b>	<b>T1C1</b>	<b>T1C0</b>	<b>Reset value: 1111b</b>

Bit 3 = MSB, Bit 0 = LSB

<b>T1RM</b>	<b>Timer 1 Restart Mode</b>	T1RM = 0, write access without Timer 1 restart T1RM = 1, write access with Timer 1 restart <b>Note:</b> if WDL = 0, Timer 1 restart is impossible
<b>T1C2</b>	<b>Timer 1 Control bit 2</b>	
<b>T1C1</b>	<b>Timer 1 Control bit 1</b>	
<b>T1C0</b>	<b>Timer 1 Control bit 0</b>	

The three bits T1C[2:0] select the divider for Timer 1. The resulting time interval depends on this divider and the Timer 1 input clock source. The timer input can be supplied by the system clock, the 32-kHz oscillator or via clock management. If the clock management generates the SUBCL, the selected input clock from the RC-oscillator, 4-MHz oscillator or an external clock is divided by 16.

**Table 13.** Timer 1 Control Bits

## Watchdog Control Register (WDC)

Address: '7'hex - Subaddress: 'A'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>WDC</b>	<b>WDL</b>	<b>WDR</b>	<b>WDT1</b>	<b>WDT0</b>	<b>Reset value: 1111b</b>

Bit 3 = MSB, Bit 0 = LSB

- WDL**     **WatchDog Lock mode**  
WDL = 1, the watchdog can be enabled and disabled by using the WDR-bit  
WDL = 0, the watchdog is enabled and locked. In this mode the WDR-bit has no effect. After the WDL-bit is cleared, the watchdog is active until a system reset or power-on reset occurs.
- WDR**     **WatchDog Run and stop mode**  
WDR = 1, the watchdog is stopped/disabled  
WDR = 0, the watchdog is active/enabled
- WDT1**     **WatchDog Time 1**
- WDT0**     **WatchDog Time 0**

Both these bits control the time interval for the watchdog reset

**Table 14.** Watchdog Time Control Bits

WDT1	WDT0	Divider	Delay Time to Reset with $t_{in} = 1/32 \text{ kHz}$	Delay Time to Reset with $t_{in} = 1/(2/1 \text{ MHz})$
0	0	512	15.625 ms	0.256 ms/0.512 ms
0	1	2048	62.5 ms	1.024 ms/2.048 ms
1	0	16384	0.5 s	8.2 ms/16.4 ms
1	1	131072	4 s	65.5 ms/131 ms

Note:  $t_{in}$ : input clock period =  $1/C_{in}$  (see Figure 14 on page 14)

## Timer 2

Timer 2 is an 8-/12-bit timer used for:

- Interrupt, square-wave, pulse and duty cycle generation
- Baud-rate generation for the internal shift register
- Manchester and Bi-phase modulation together with the SSI
- Carrier frequency generation and modulation together with the SSI

Timer 2 can be used as an interval timer for interrupt generation, as signal generator or as baud-rate generator and modulator for the serial interface. It consists of a 4-bit and an 8-bit up counter stage which both have compare registers. The 4-bit counter stages of Timer 2 are cascadable as a 12-bit timer or as an 8-bit timer with a 4-bit prescaler. The timer can also be configured as an 8-bit timer and a separate 4-bit prescaler.

The Timer 2 input can be supplied via the system clock, the external input clock (T2I), the Timer 1 output clock or the shift clock of the serial interface. The external input clock T2I is not synchronized with SYSCL. Therefore, it is possible to use Timer 2 with a higher clock speed than SYSCL. Furthermore, with that input clock Timer 2 operates in the power-down mode SLEEP (CPU core →sleep and OSC-Stop →yes) as well as in the POWER-DOWN (CPU core →sleep and OSC-Stop →no). All other clock sources supply no clock signal in SLEEP if NSTOP = 0. The 4-bit counter stages of Timer 2 have an additional clock output (POUT).

Its output has a modulator stage that allows the generation of pulses as well as the generation and modulation of carrier frequencies. Timer 2 output can modulate with the shift register internal data output to generate Bi-phase- or Manchester-code.

If the serial interface is used to modulate a bit-stream, the 4-bit stage of Timer 2 has a special task. The shift register can only handle bit-stream lengths divisible by 8. For other lengths, the 4-bit counter stage can be used to stop the modulator after the right bit-count is shifted out.

If the timer is used for carrier frequency modulation, the 4-bit stage works together with an additional 2-bit duty cycle generator like a 6-bit prescaler to generate carrier frequency and duty cycle. The 8-bit counter is used to enable and disable the modulator output for a programmable count of pulses.

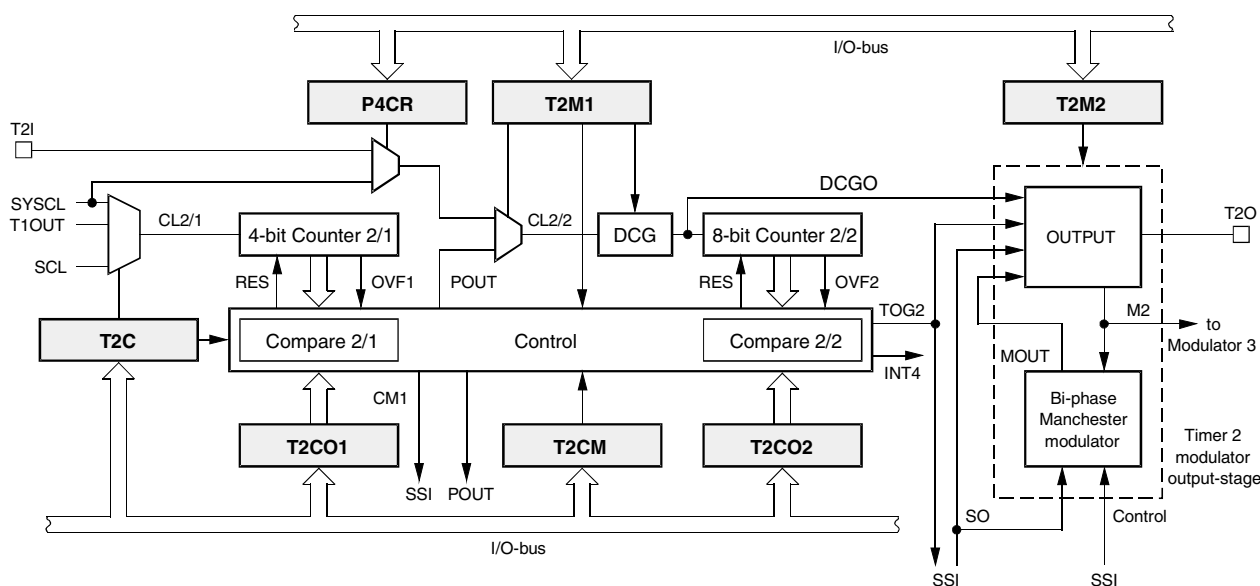

The timer has a 4-bit and an 8-bit compare register for programming the time interval: For programming the timer function, it has four mode and control registers. The comparator output of stage 2 is controlled by a special compare mode register (T2CM). This register contains mask bits for the actions (counter reset, output toggle, timer interrupt) which can be triggered by a compare match event or the counter overflow. This architecture enables the timer to function for various modes.

Timer 2 compare data values.

Timer 2 has a 4-bit compare register (T2CO1) and an 8-bit compare register (T2CO2). Both these compare registers are cascadable as a 12-bit compare register, or 8-bit compare register and 4-bit compare register.

- For 12-bit compare data value:  $m = x + 1$ ;  $0 \leq x \leq 4095$
- For 8-bit compare data value:  $n = y + 1$ ;  $0 \leq y \leq 255$
- For 4-bit compare data value:  $l = z + 1$ ;  $0 \leq z \leq 15$

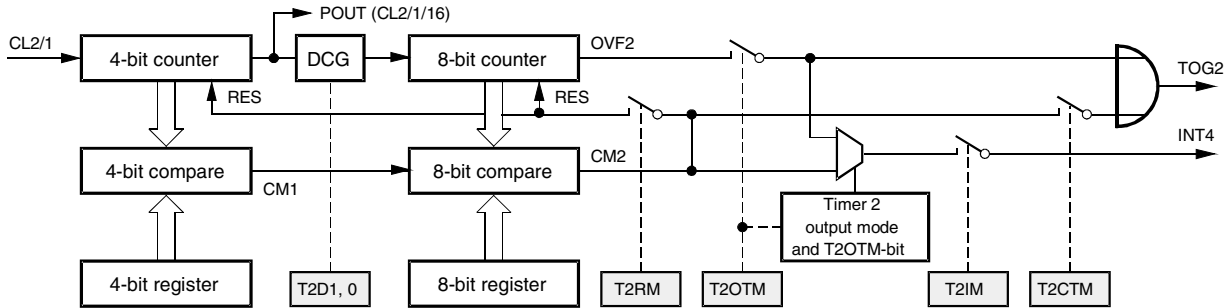

**Figure 29.** Timer 2

### Mode 1: 12-bit Compare Counter

The 4-bit stage and the 8-bit stage work together as a 12-bit compare counter. A compare match signal of the 4-bit and the 8-bit stage generates the signal for the counter reset, toggle flip-flop or interrupt. The compare action is programmable via the compare mode register (T2CM). The 4-bit counter overflow (OVF1) supplies the clock output (POUT) with clocks. The duty cycle generator (DCG) has to be bypassed in this mode.

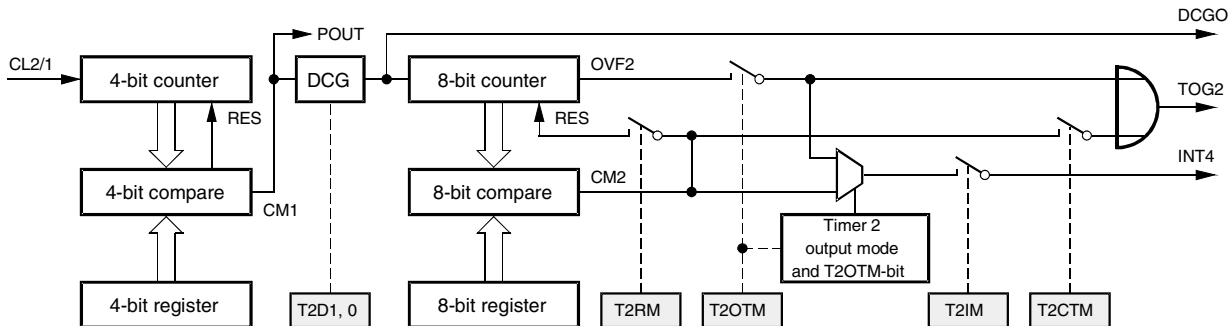

**Figure 30.** 12-bit Compare Counter

### Mode 2: 8-bit Compare Counter with 4-bit Programmable Prescaler

The 4-bit stage is used as a programmable prescaler for the 8-bit counter stage. In this mode, a duty cycle stage is also available. This stage can be used as an additional 2-bit prescaler or for generating duty cycles of 25%, 33% and 50%. The 4-bit compare output (CM1) supplies the clock output (POUT) with clocks.

**Figure 31.** 8-bit Compare Counter

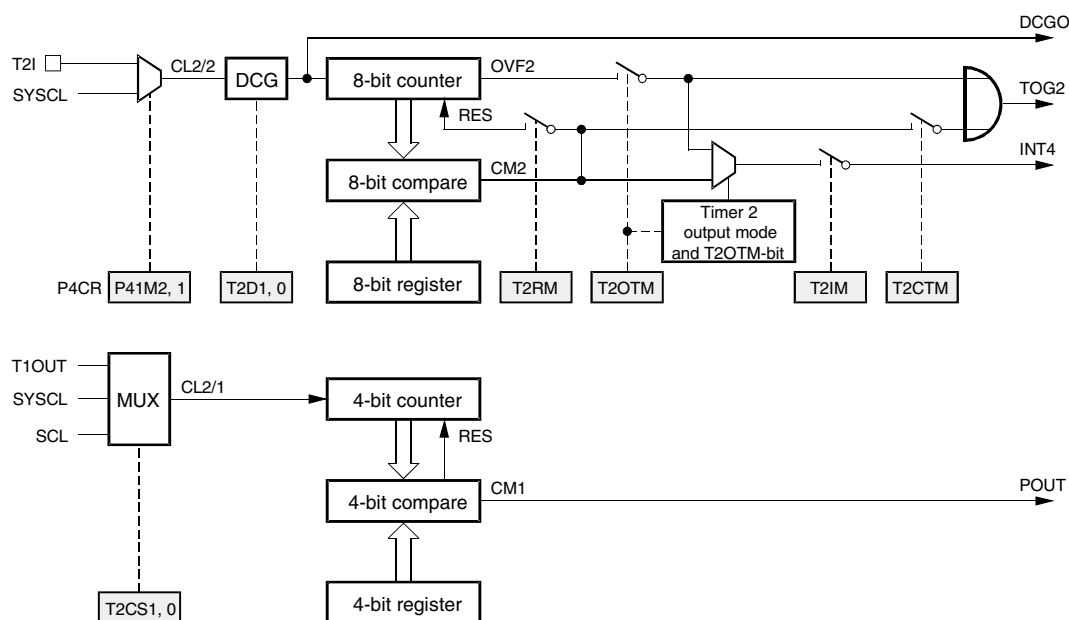

### Mode 3/4: 8-bit Compare Counter and 4-bit Programmable Prescaler

In these modes the 4-bit and the 8-bit counter stages work independently as a 4-bit prescaler and an 8-bit timer with a 2-bit prescaler or as a duty cycle generator. Only in mode 3 and mode 4 can the 8-bit counter be supplied via the external clock input (T2I) which is selected via the P4CR register. The 4-bit prescaler is started by activating of mode 3 and stopped and reset in mode 4. Changing mode 3 and 4 has no effect for the 8-bit timer stage. The 4-bit stage can be used as a prescaler for the SSI or to generate the stop signal for modulator 2.

**Figure 32. 4-/8-bit Compare Counter**

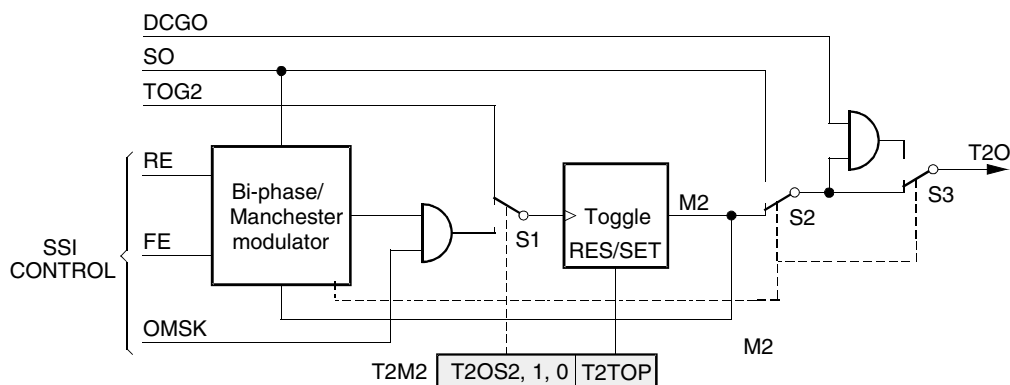

## Timer 2 Output Modes

The signal at the timer output is generated via modulator 2. In the toggle mode, the compare match event toggles the output T2O. For high resolution duty cycle modulation 8 bits or 12 bits can be used to toggle the output. In the duty cycle burst modulator modes the DCG output is connected to T2O and switched on and off either by the toggle flipflop output or the serial data line of the SSI. Modulator 2 also has two modes to output the content of the serial interface as Bi-phase or Manchester code.

The modulator output stage can be configured by the output control bits in the T2M2 register. The modulator is started with the start of the shift register (SIR = 0) and stopped either by carrying out a shift register stop (SIR = 1) or compare match event of stage 1 (CM1) of Timer 2. For this task, Timer 2 mode 3 must be used and the prescaler has to be supplied with the internal shift clock (SCL).

**Figure 33.** Timer 2 Modulator Output Stage

## Timer 2 Output Mode 1

**Toggle Mode A:** A Timer 2 compare match toggles the output flip-flop (M2) → T2O

**Figure 34.** Interrupt Timer/Square Wave Generator - the Output Toggles with Each Edge Compare Match Event

**Toggle Mode B:** A Timer 2 compare match toggles the output flip-flop (M2) → T2O

**Figure 35.** Pulse Generator - the Timer Output Toggles with the Timer Start if the T2TS-bit is Set

**Toggle Mode C:** A Timer 2 compare match toggles the output flip-flop (M2) → T2O

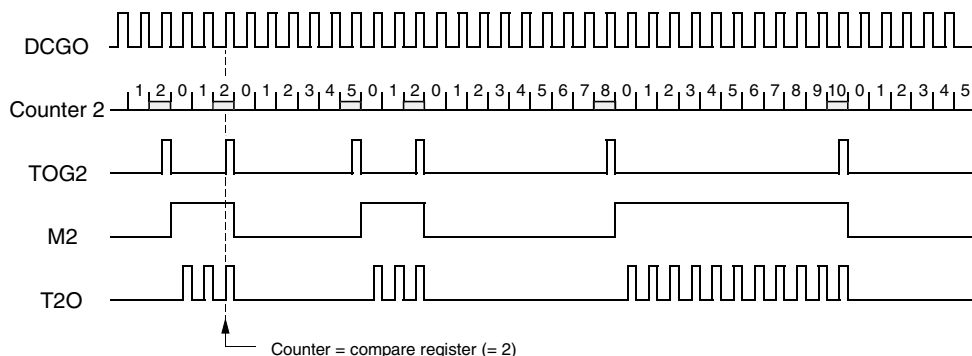

**Figure 36.** Pulse Generator – Timer Toggles with Timer Overflow and Compare Match

## Timer 2 Output Mode 2

**Duty Cycle Burst Generator 1:** The DCG output signal (DCGO) is given to the output, and gated by the output flip-flop (M2).

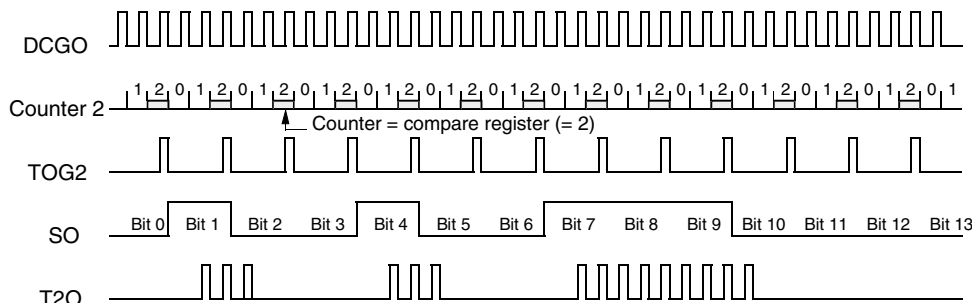

**Figure 37.** Carrier Frequency Burst Modulation with Timer 2 Toggle Flip-flop Output

## Timer 2 Output Mode 3

**Duty Cycle Burst Generator 2:** The DCG output signal (DCGO) is given to the output, and gated by the SSI internal data output (SO).

**Figure 38.** Carrier Frequency Burst Modulation with the SSI Data Output

## Timer 2 Output Mode 4

**Bi-phase Modulator:** Timer 2 modulates the SSI internal data output (SO) to Bi-phase code.

**Figure 39.** Bi-phase Modulation

## Timer 2 Output Mode 5

**Manchester Modulator:** Timer 2 modulates the SSI internal data output (SO) to Manchester code.

**Figure 40.** Manchester Modulation

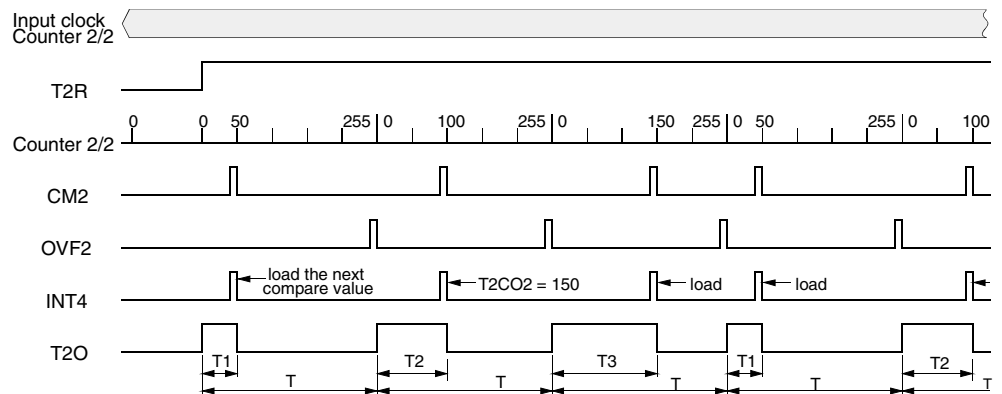

## Timer 2 Output Mode 7

**PWM Mode:** Pulse-width modulation output on Timer 2 output pin (T2O).

In this mode the timer overflow defines the period and the compare register defines the duty cycle. During one period only the first compare match occurrence is used to toggle the timer output flip-flop, until overflow occurs all further compare match are ignored. This avoids the situation that changing the compare register causes the occurrence of several compare match during one period. The resolution at the pulse-width modulation Timer 2 mode 1 is 12-bit and all other Timer 2 modes are 8-bit.

**Figure 41.** PWM Modulation

## Timer 2 Registers

Timer 2 has 6 control registers to configure the timer mode, the time interval, the input clock and its output function. All registers are indirectly addressed using extended addressing as described in section "Addressing Peripherals". The alternate functions of the Ports BP41 or BP42 must be selected with the Port 4 control register P4CR, if one of the Timer 2 modes require an input at T2I/BP41 or an output at T2O/BP42.

## Timer 2 Control Register (T2C)

Address: '7'hex - Subaddress: '0'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>T2C</b>	<b>T2CS1</b>	<b>T2CS0</b>	<b>T2TS</b>	<b>T2R</b>	<b>Reset value: 0000b</b>

**T2CS1** Timer 2 Clock Select bit 1

**T2CS0** Timer 2 Clock Select bit 0

**Table 15.** Timer 2 Clock Select Bits

<b>T2CS1</b>	<b>T2CS0</b>	<b>Input Clock (CL 2/1) of Counter Stage 2/1</b>
0	0	System clock (SYSCL)
0	1	Output signal of Timer 1 (T1OUT)
1	0	Internal shift clock of SSI (SCL)
1	1	Reserved

**T2TS** Timer 2 Toggle with Start

T2TS = 0, the output flip-flop of Timer 2 is not toggled with the timer start

T2TS = 1, the output flip-flop of Timer 2 is toggled when the timer is started with T2R

**T2R** Timer 2 Run

T2R = 0, Timer 2 stop and reset

T2R = 1, Timer 2 run

## Timer 2 Mode Register 1 (T2M1)

Address: '7'hex - Subaddress: '1'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>T2M1</b>	<b>T2D1</b>	<b>T2D0</b>	<b>T2MS1</b>	<b>T2MS0</b>	<b>Reset value: 1111b</b>

**T2D1** Timer 2 Duty cycle bit 1

**T2D0** Timer 2 Duty cycle bit 0

**Table 16.** Timer 2 Duty Cycle Bits

<b>T2D1</b>	<b>T2D0</b>	<b>Function of Duty Cycle Generator (DCG)</b>	<b>Additional Divider Effect</b>
1	1	Bypassed (DCGO0)	/1
1	0	Duty cycle 1/1 (DCGO1)	/2
0	1	Duty cycle 1/2 (DCGO2)	/3
0	0	Duty cycle 1/3 (DCGO3)	/4

**T2MS1** Timer 2 Mode Select bit 1  
**T2MS0** Timer 2 Mode Select bit 0

**Table 17.** Timer 2 Mode Select Bits

Mode	T2MS1	T2MS0	Clock Output (POUT)	Timer 2 Modes
1	1	1	4-bit counter overflow (OVF1)	12-bit compare counter, the DCG have to be bypassed in this mode
2	1	0	4-bit compare output (CM1)	8-bit compare counter with 4-bit programmable prescaler and duty cycle generator
3	0	1	4-bit compare output (CM1)	8-bit compare counter clocked by SYSCL or the external clock input T2I, 4-bit prescaler run, the counter 2/1 starts after writing mode 3
4	0	0	4-bit compare output (CM1)	8-bit compare counter clocked by SYSCL or the external clock input T2I, 4-bit prescaler stop and resets

#### Duty Cycle Generator

The duty cycle generator generates duty cycles from 25%, 33% or 50%. The frequency at the duty cycle generator output depends on the duty cycle and the Timer 2 prescaler setting. The DCG-stage can also be used as an additional programmable prescaler for Timer 2.

**Figure 42.** DCG Output Signals

## Timer 2 Mode Register 2 (T2M2)

Address: '7'hex - Subaddress: '2'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
T2M2	T2TOP	T2OS2	T2OS1	T2OS0	Reset value: 1111b

- T2TOP** Timer 2 Toggle Output Preset  
This bit allows the programmer to preset the Timer 2 output T2O.  
T2TOP = 0, resets the toggle outputs with the write cycle (M2 = 0)  
T2TOP = 1, sets toggle outputs with the write cycle (M2 = 1)  
**Note: If T2R = 1, no output preset is possible**
- T2OS2** Timer 2 Output Select bit 2
- T2OS1** Timer 2 Output Select bit 1
- T2OS0** Timer 2 Output Select bit 0

**Table 18.** Timer 2 Output Select Bits

Output Mode	T2OS2	T2MS1	T2MS0	Clock Output
1	1	1	1	Toggle mode: a Timer 2 compare match toggles the output flip-flop (M2) →T2O
2	1	1	0	Duty cycle burst generator 1: the DCG output signal (DCG0) is given to the output and gated by the output flip-flop (M2)
3	1	0	1	Duty cycle burst generator 2: the DCG output signal (DCGO) is given to the output and gated by the SSI internal data output (SO)
4	1	0	0	Bi-phase modulator: Timer 2 modulates the SSI internal data output (SO) to Bi-phase code
5	0	1	1	Manchester modulator: Timer 2 modulates the SSI internal data output (SO) to Manchester code
6	0	1	0	SSI output: T2O is used directly as SSI internal data output (SO)
7	0	0	1	PWM mode: an 8/12-bit PWM mode
8	0	0	0	Not allowed

**Note:** If one of these output modes is used, the T2O alternate function of Port 4 must also be activated.

## Timer 2 Compare and Compare Mode Registers

Timer 2 has two separate compare registers, T2CO1 for the 4-bit stage and T2CO2 for the 8-bit stage of Timer 2. The timer compares the contents of the compare register current counter value, and if it matches, it generates an output signal. Depending on the timer mode, this signal is used to generate a timer interrupt, to toggle the output flip-flop as SSI clock or as a clock for the next counter stage.

In the 12-bit timer mode, T2CO1 contains bits 0 to 3 and T2CO2 bits 4 to 11 of the 12-bit compare value. In all other modes, the two compare registers work independently as a 4- and 8-bit compare register. When assigned to the compare register a compare event will be suppressed.

## Timer 2 Compare Mode Register (T2CM)

Address: '7'hex - Subaddress: '3'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>T2CM</b>	<b>T2OTM</b>	<b>T2CTM</b>	<b>T2RM</b>	<b>T2IM</b>	<b>Reset value: 0000b</b>
<b>T2OTM</b>	<b>Timer 2 Overflow Toggle Mask bit</b> T2OTM = 0, disable overflow toggle T2OTM = 1, enable overflow toggle, a counter overflow (OVF2) toggles the output flip-flop (TOG2). If the T2OTM-bit is set, only a counter overflow can generate an interrupt except on the Timer 2 output mode 7.				
<b>T2CTM</b>	<b>Timer 2 Compare Toggle Mask bit</b> T2CTM = 0, disable compare toggle T2CTM = 1, enable compare toggle, a match of the counter with the compare register toggles output flip-flop (TOG2). In Timer 2 output mode 7 and when the T2CTM-bit is set, only a match of the counter with the compare register can generate an interrupt.				
<b>T2RM</b>	<b>Timer 2 Reset Mask bit</b> T2RM = 0, disable counter reset T2RM = 1, enable counter reset, a match of the counter with the compare register resets the counter				
<b>T2IM</b>	<b>Timer 2 Interrupt Mask bit</b> T2IM = 0, disable Timer 2 interrupt T2IM = 1, enable Timer 2 interrupt				

**Table 19.** Timer 2 Toggle Mask Bits

Timer 2 Output Mode	T2OTM	T2CTM	Timer 2 Interrupt Source
1, 2, 3, 4, 5 and 6	0	x	Compare match (CM2)
1, 2, 3, 4, 5 and 6	1	x	Overflow (OVF2)
7	x	1	Compare match (CM2)

## Timer 2 COmpare Register 1 (T2CO1)

Address: '7'hex -Subaddress: '4'hex

<b>T2CO1</b>	<b>Write cycle</b>	<b>Bit 3</b>	<b>Bit 2</b>	<b>Bit 1</b>	<b>Bit 0</b>	<b>Reset value: 1111b</b>

In prescaler mode the clock is bypassed if the compare register T2CO1 contains 0.

## Timer 2 COmpare Register 2 (T2CO2) Byte Write

Address: '7'hex - Subaddress: '5'hex

<b>T2CO2</b>	<b>First write cycle</b>	<b>Bit 3</b>	<b>Bit 2</b>	<b>Bit 1</b>	<b>Bit 0</b>	<b>Reset value: 1111b</b>
	<b>Second write cycle</b>	<b>Bit 7</b>	<b>Bit 6</b>	<b>Bit 5</b>	<b>Bit 4</b>	<b>Reset value: 1111b</b>

## Synchronous Serial Interface (SSI)

### SSI Features

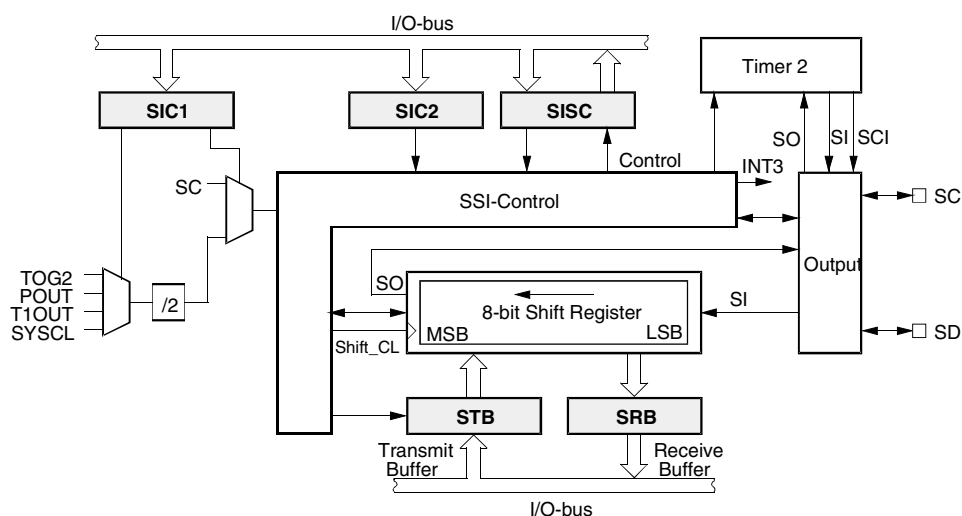

- 2- and 3-wire NRZ
- 2-wire mode
- With Timer 2
  - Bi-phase modulation
  - Manchester modulation
  - Pulse-width demodulation
  - Burst modulation

### SSI Peripheral Configuration

The synchronous serial interface (SSI) can be used either for serial communication with external devices such as EEPROMs, shift registers, display drivers, other microcontrollers, or as a means for generating and capturing on-chip serial streams of data. External data communication takes place via Port 4 (BP4) multi-functional port which can be software configured by writing the appropriate control word into the P4CR register. The SSI can be configured in any one of the following ways:

1. 2-wire external interface for bi-directional data communication with one data terminal and one shift clock. The SSI uses Port BP43 as a bi-directional serial data line (SD) and BP40 as a shift clock line (SC).
2. 3-wire external interface for simultaneous input and output of serial data, with a serial input data terminal (SI), a serial output data terminal (SO) and a shift clock (SC). The SSI uses BP40 as a shift clock (SC), while the serial data input (SI) is applied to BP43 (configured in P4CR as input). Serial output data (SO) in this case is passed through to BP42 (configured in P4CR to T2O) via Timer 2 output stage (T2M2 configured in mode 6).
3. Timer/SSI combined modes – the SSI used together with Timer 2 is capable of performing a variety of data modulation and functions (see section “Timer”. The modulating data is converted by the SSI into a continuous serial stream of data which is in turn modulated in one of the timer functional blocks.

**Figure 43.** Block Diagram of the Synchronous Serial Interface

## General SSI Operation

The SSI is comprised essentially of an 8-bit shift register with two associated 8-bit buffers - the receive buffer (SRB) for capturing the incoming serial data and a transmit buffer (STB) for intermediate storage of data to be serially output. Both buffers are directly accessible by software. Transferring the parallel buffer data into and out of the shift register is controlled automatically by the SSI control, so that both single byte transfers or continuous bit-streams can be supported.

The SSI can generate the shift clock (SC) from one of several on-chip clock sources or it can accept an external clock. The external shift clock is output on, or applied to the Port BP40. Selection of an external clock source is performed by the Serial Clock Direction control bit (SCD). In the combinational modes, the required clock is selected by the corresponding timer mode.

The SSI can operate in three data transfer modes – synchronous 8-bit shift mode, 9-bit MCL shift modes or 8-bit pseudo MCL protocol (without acknowledge-bit).

External SSI clocking is not supported in these modes. The SSI should thus generate and have full control over the shift clock so that it can always be regarded as an MCL Bus Master device.

All directional control of the external data port used by the SSI is handled automatically and is dependent on the transmission direction set by the Serial Data Direction (SDD) control bit. This control bit defines whether the SSI is currently operating in Transmit (TX) mode or Receive (RX) mode.

Serial data is organized in 8-bit telegrams which are shifted with the most significant bit first. In the 9-bit MCL mode, an additional acknowledge bit is appended to the end of the telegram for handshaking purposes (see "MCL Protocol").

At the beginning of every telegram, the SSI control loads the transmit buffer into the shift register and proceeds immediately to shift data serially out. At the same time, incoming data is shifted into the shift register input. This incoming data is automatically loaded into the receive buffer when the complete telegram has been received. Data can, if required thus be simultaneously received and transmitted.

Before data can be transferred, the SSI must first be activated. This is performed by means of the SSI reset control (SIR) bit. All further operation then depends on the data directional mode (TX/RX) and the present status of the SSI buffer registers shown by the Serial Interface Ready Status Flag (SRDY). This SRDY flag indicates the (empty/full) status of either the transmit buffer (in TX mode), or the receive buffer (in RX mode). The control logic ensures that data shifting is temporarily halted at any time, if the appropriate receive/transmit buffer is not ready (SRDY = 0). The SRDY status will then automatically be set back to '1' and data shifting resumed as soon as the application software loads the new data into the transmit register (in TX mode) or frees the shift register by reading it into the receive buffer (in RX mode).

A further activity status (ACT) bit indicates the present status of serial communication. The ACT bit remains high for the duration of the serial telegram or if MCL stop or start conditions are currently being generated. Both the current SRDY and ACT status can be read in the SSI status register. To deactivate the SSI, the SIR bit must be set high.

8-bit Synchronous Mode

Figure 44. 8-bit Synchronous Mode

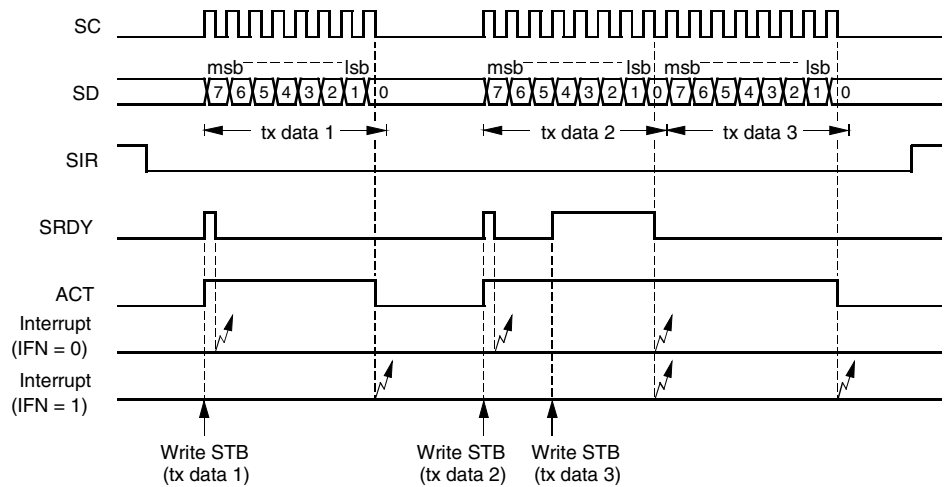

In the 8-bit synchronous mode, the SSI can operate as either a 2- or 3-wire interface (see section “SSI Peripheral Configuration”). The serial data (SD) is received or transmitted in NRZ format, synchronized to either the rising or falling edge of the shift clock (SC). The choice of clock edge is defined by the Serial Mode Control bits (SM0, SM1). It should be noted that the transmission edge refers to the SC clock edge with which the SD changes. To avoid clock skew problems, the incoming serial input data is shifted in with the opposite edge.

When used together with one of the timer modulator or demodulator stages, the SSI must be set in the 8-bit synchronous mode 1.

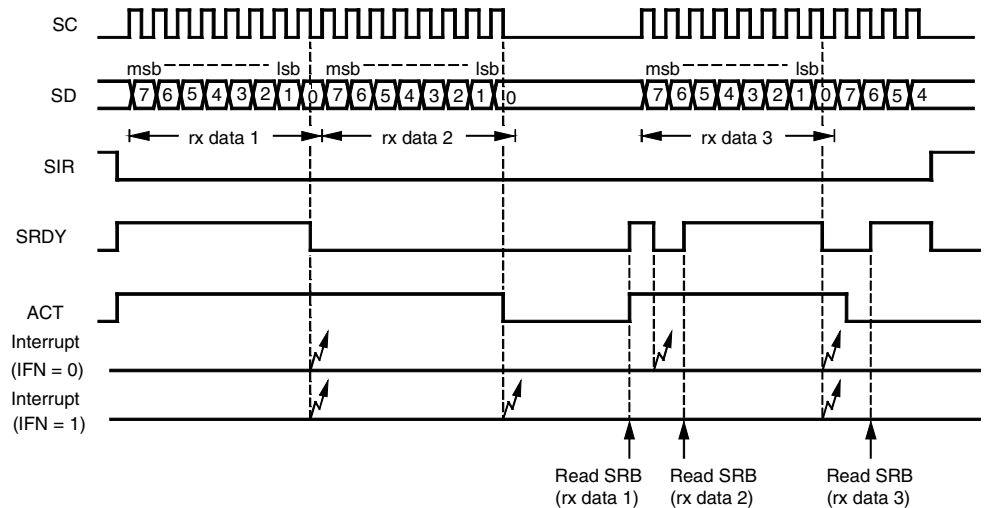

In RX mode, as soon as the SSI is activated ( $SIR = 0$ ), 8 shift clocks are generated and the incoming serial data is shifted into the shift register. This first telegram is automatically transferred into the receive buffer and the SRDY flag is set to 0 indicating that the receive buffer contains valid data. At the same time an interrupt (if enabled) is generated. The SSI then continues shifting in the following 8-bit telegram. If, during this time the first telegram has been read by the controller, the second telegram will also be transferred in the same way into the receive buffer and the SSI will continue clocking in the next telegram. Should, however, the first telegram not have been read ( $SRDY = 1$ ), then the SSI will stop, temporarily holding the second telegram in the shift register until a certain point in time when the controller is able to service the receive buffer. In this way no data is lost or overwritten.

Deactivating the SSI ( $SIR = 1$ ) in mid-telegram will immediately stop the shift clock and latch the present contents of the shift register into the receive buffer. This can be used for clocking in a data telegram of less than 8 bits in length. Care should be taken to read out the final complete 8-bit data telegram of a multiple word message before deactivating the SSI ( $SIR = 1$ ) and terminating the reception. After termination, the shift register contents will overwrite the receive buffer.

**Figure 45.** Example of 8-bit Synchronous Transmit Operation

**Figure 46.** Example of 8-bit Synchronous Receive Operation

### 9-bit Shift Mode

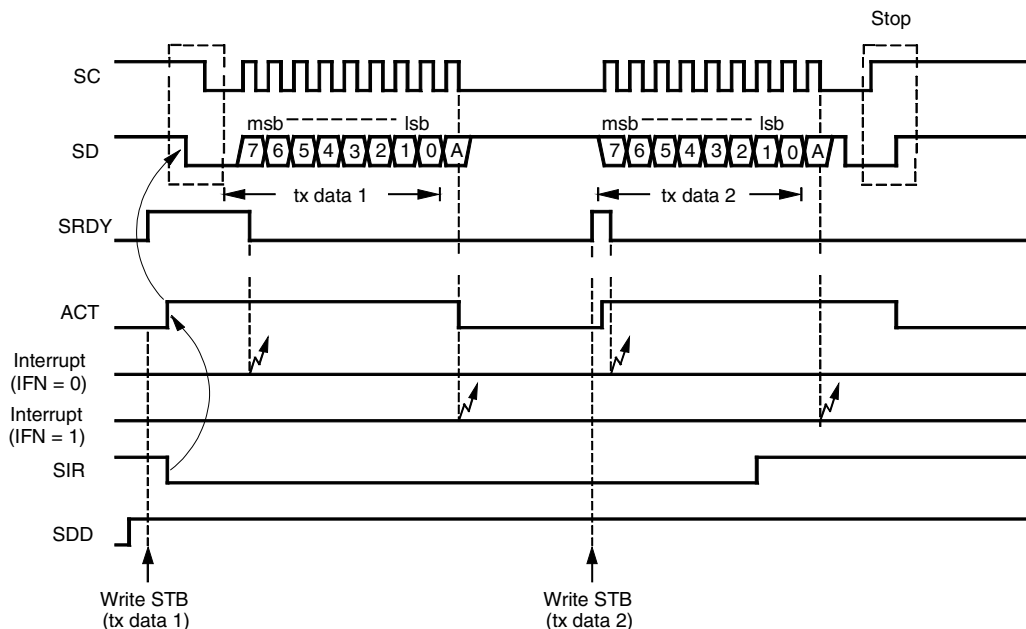

In the 9-bit shift mode, the SSI is able to handle the MCL protocol (described below). It always operates as an MCL master device, i.e., SC is always generated and output by the SSI. Both the MCL start and stop conditions are automatically generated whenever the SSI is activated or deactivated by the SIR-bit. In accordance with the MCL protocol, the output data is always changed in the clock low phase and shifted in on the high phase.

Before activating the SSI ( $SIR = 0$ ) and commencing an MCL dialog, the appropriate data direction for the first word must be set using the SDD control bit. The state of this bit controls the direction of the data port (BP43 or SD). Once started, the 8 data bits are, depending on the selected direction, either clocked into or out of the shift register. During the 9th clock period, the port direction is automatically switched over so that the corresponding acknowledge bit can be shifted out or read in. In transmit mode, the acknowledge bit received from the device is captured in the SSI Status Register (TACK) where it can be read by the controller. In receive mode, the state of the acknowledge bit to be returned to the device is predetermined by the SSI Status Register (RACK).

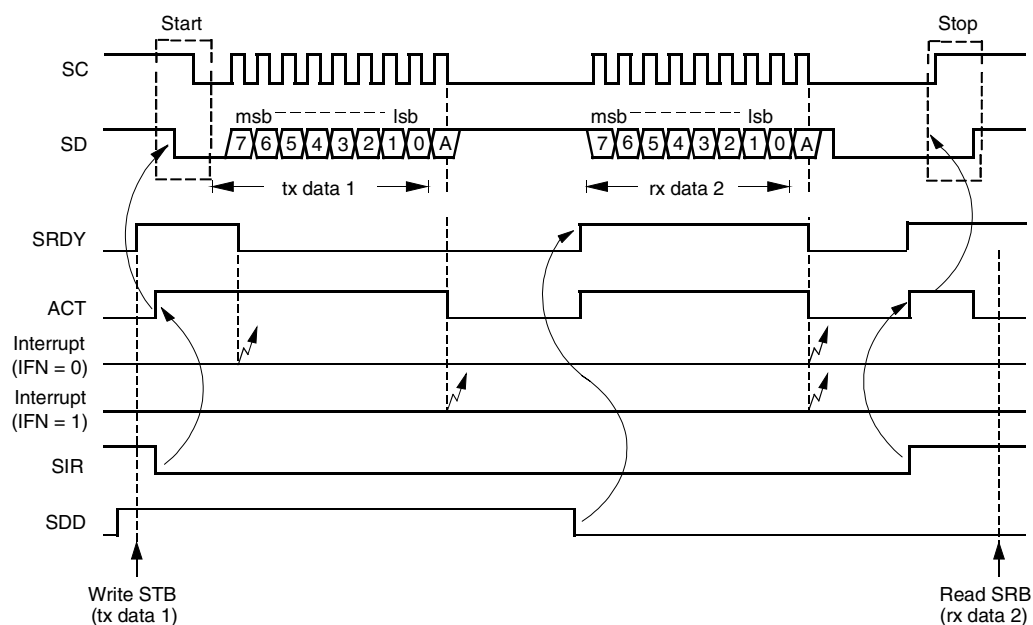

Changing the directional mode (TX/RX) should not be performed during the transfer of an MCL telegram. One should wait until the end of the telegram which can be detected using the SSI interrupt (IFN = 1) or by interrogating the ACT status.

A 9-bit telegram, once started will always run to completion and will not be prematurely terminated by the SIR bit. So, if the SIR-bit is set to '1' in mid telegram, the SSI will complete the current transfer and terminate the dialog with an MCL stop condition.

**Figure 47.** Example of MCL Transmit Dialog

**Figure 48.** Example of MCL Receive Dialog

## 8-bit Pseudo MCL Mode

In this mode, the SSI exhibits all the typical MCL operational features except for the acknowledge-bit which is never expected or transmitted.

## MCL Bus Protocol

The MCL protocol constitutes a simple 2-wire bi-directional communication highway via which devices can communicate control and data information. Although the MCL protocol can support multi-master bus configurations, the SSI, in MCL mode is intended for use purely as a master controller on a single master bus system. So all reference to multiple bus control and bus contention will be omitted at this point.

All data is packaged into 8-bit telegrams plus a trailing handshaking or acknowledge-bit. Normally the communication channel is opened with a so-called start condition, which initializes all devices connected to the bus. This is then followed by a data telegram, transmitted by the master controller device. This telegram usually contains an 8-bit address code to activate a single slave device connected onto the MCL bus. Each slave receives this address and compares it with its own unique address. The addressed slave device, if ready to receive data will respond by pulling the SD line low during the 9th clock pulse. This represents a so-called MCL acknowledge. The controller on detecting this affirmative acknowledge then opens a connection to the required slave. Data can then be passed back and forth by the master controller, each 8-bit telegram being acknowledged by the respective recipient. The communication is finally closed by the master device and the slave device put back into standby by applying a stop condition onto the bus.

**Figure 49.** MCL Bus Protocol 1

### Bus not busy (1)

Both data and clock lines remain HIGH.

### Start data transfer (2)

A HIGH to LOW transition of the SD line while the clock (SC) is HIGH defines a START condition.

### Stop data transfer (3)

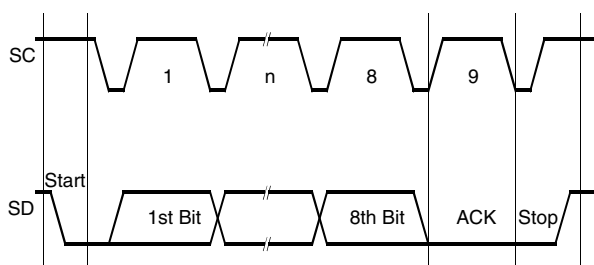

A LOW to HIGH transition of the SD line while the clock (SC) is HIGH defines a STOP condition.

### Data valid (4)

The state of the data line represents valid data when, after a START condition, the data line is stable for the duration of the HIGH period of the clock signal.

### Acknowledge

All address and data words are serially transmitted to and from device in eight-bit words. The receiving device returns a zero on the data line during the ninth clock cycle to acknowledge word receipt.

**Figure 50. MCL Bus Protocol 2**

### *SSI Interrupt*

The SSI interrupt INT3 can be generated either by an SSI buffer register status (i.e., transmit buffer empty or receive buffer full) at the end of an SSI data telegram or on the falling edge of the SC/SD pins on Port 4 (see P4CR). SSI interrupt selection is performed by the Interrupt Function control bit (IFN). The SSI interrupt is usually used to synchronize the software control of the SSI and inform the controller of the present SSI status. Port 4 interrupts can be used together with the SSI or, if the SSI itself is not required, as additional external interrupt sources. In either case this interrupt is capable of waking the controller out of sleep mode.

To enable and select the SSI relevant interrupts use the SSI interrupt mask (SIM) and the Interrupt Function (IFN) while Port 4 interrupts are enabled by setting appropriate control bits in P4CR register.

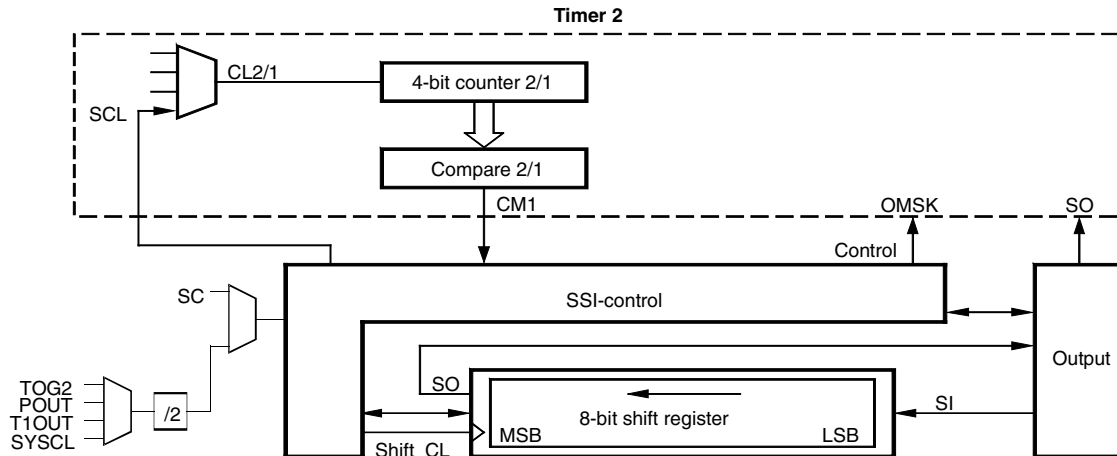

### *Modulation*

If the shift register is used together with Timer 2 for modulation purposes, the 8-bit synchronous mode must be used. In this case, the unused Port 4 pins can be used as conventional bi-directional ports.

The modulation stage, if enabled, operates as soon as the SSI is activated (SIR = 0) and ceases when deactivated (SIR = 1).

Due to the byte-orientated data control, the SSI (when running normally) generates serial bit-streams which are submultiples of 8 bits. However, an SSI output masking (OMSK) function permits the generation of bit-streams of any length. The OMSK signal is derived indirectly from the 4-bit prescaler of the Timer 2 and masks out a programmable number of unrequired trailing data bits during the shifting out of the final data word in the bit stream. The number of non-masked data bits is defined by the value pre-programmed in the prescaler compare register. To use output masking, the modulator stop mode bit (MSM) must be set to '0' before programming the final data word into the SSI transmit buffer. This in turn, enables shift clocks to the prescaler when this final word is shifted out. On reaching the compare value, the prescaler triggers the OMSK signal and all following data bits are blanked.

**Figure 51. SSI Output Masking Function**

## Serial Interface Registers

### Serial Interface Control Register 1 (SIC1)

Auxiliary register address: '9'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>SIC1</b>	<b>SIR</b>	<b>SCD</b>	<b>SCS1</b>	<b>SCS0</b>	<b>Reset value: 1111b</b>

- SIR**      **Serial Interface Reset**  
SIR = 1, SSI inactive  
SIR = 0, SSI active
- SCD**      **Serial Clock Direction**  
SCD = 1, SC line used as output  
SCD = 0, SC line used as input  
**Note:** This bit has to be set to '1' during the MCL mode
- SCS1**      **Serial Clock source Select bit 1**
- SCS0**      **Serial Clock source Select bit 0**
- Note:**      With SCD = '0' the bits SCS1 and SCS0 are insignificant

**Table 20. Serial Clock Source Select Bits**

SCS1	SCS0	Internal Clock for SSI
1	1	YSCL/2
1	0	T1OUT/2
0	1	POUT/2
0	0	TOG2/2

- In transmit mode (SDD = 1) shifting starts only if the transmit buffer has been loaded (SRDY = 1).
- Setting SIR-bit loads the contents of the shift register into the receive buffer (synchronous 8-bit mode only).
- In MCL modes, writing a 0 to SIR generates a start condition and writing a 1 generates a stop condition.

Serial Interface Control Register  
2 (SIC2)

Auxiliary register address: 'A'hex

	Bit 3	Bit 2	Bit 1	Bit 0	
<b>SIC2</b>	<b>MSM</b>	<b>SM1</b>	<b>SM0</b>	<b>SDD</b>	<b>Reset value: 1111b</b>

**MSM**      **Modular Stop Mode**  
 MSM = 1, modulator stop mode disabled (output masking off)  
 MSM = 0, modulator stop mode enabled (output masking on) - used in modulation modes for generating bit-streams which are not sub-multiples of 8 bits.

**SM1**      **Serial Mode control bit 1**

**SM0**      **Serial Mode control bit 0**

**Table 21.** Serial Mode Control Bits

Mode	SM1	SM0	SSI Mode
1	1	1	8-bit NRZ-data changes with the rising edge of SC
2	1	0	8-bit NRZ-data changes with the falling edge of SC
3	0	1	9-bit two-wire MCL mode
4	0	0	8-bit two-wire pseudo MCL mode (no acknowledge)

**SDD**      **Serial Data Direction**  
 SDD = 1, transmit mode – SD line used as output (transmit data). SRDY is set by a transmit buffer write access  
 SDD = 0, receive mode – SD line used as input (receive data). SRDY is set by a receive buffer read access

Note: SDD controls port directional control and defines the reset function for the SRDY-flag

## Serial Interface Status and Control Register (SISC)

Primary register address: 'A'hex

		Bit 3	Bit 2	Bit 1	Bit 0	
SISC	write		<b>RACK</b>	<b>SIM</b>	<b>IFN</b>	<b>Reset value: 1111b</b>
SISC	read	–	<b>TACK</b>	<b>ACT</b>	<b>SRDY</b>	<b>Reset value: xxxxb</b>

<b>RACK</b>	Receive <b>ACK</b> nowledge status/control bit for MCL mode RACK = 0, transmit acknowledge in next receive telegram RACK = 1, transmit no acknowledge in last receive telegram
<b>TACK</b>	Transmit <b>ACK</b> nowledge status/control bit for MCL mode TACK = 0, acknowledge received in last transmit telegram TACK = 1, no acknowledge received in last transmit telegram
<b>SIM</b>	<b>S</b> erial <b>I</b> nterrupt <b>M</b> ask SIM = 1, disable interrupts SIM = 0, enable serial interrupt. An interrupt is generated.
<b>IFN</b>	<b>I</b> nterrupt <b>Fu</b> Nction IFN = 1, the serial interrupt is generated at the end of the telegram IFN = 0, the serial interrupt is generated when the SRDY goes low (i.e., buffer becomes empty/full in transmit/receive mode)
<b>SRDY</b>	<b>S</b> erial interface buffer <b>ReaDY</b> status flag SRDY = 1, in receive mode: receive buffer empty in transmit mode: transmit buffer full SRDY = 0, in receive mode: receive buffer full in transmit mode: transmit buffer empty
<b>ACT</b>	<b>T</b> ransmission <b>ACT</b> ive status flag ACT = 1, transmission is active, i.e., serial data transfer. Stop or start conditions are currently in progress. ACT = 0, transmission is inactive

## Serial Transmit Buffer (STB) – Byte Write

Primary register address: '9'hex

<b>STB</b>	<b>First write cycle</b>	<b>Bit 3</b>	<b>Bit 2</b>	<b>Bit 1</b>	<b>Bit 0</b>	<b>Reset value: xxxxb</b>
	<b>Second write cycle</b>	<b>Bit 7</b>	<b>Bit 6</b>	<b>Bit 5</b>	<b>Bit 4</b>	<b>Reset value: xxxxb</b>

The STB is the transmit buffer of the SSI. The SSI transfers the transmit buffer into the shift register and starts shifting with the most significant bit.

## Serial Receive Buffer (SRB) – Byte Read

Primary register address: '9'hex

<b>SRB</b>	<b>First read cycle</b>	<b>Bit 7</b>	<b>Bit 6</b>	<b>Bit 5</b>	<b>Bit 4</b>	<b>Reset value: xxxxb</b>
	<b>Second read cycle</b>	<b>Bit 3</b>	<b>Bit 2</b>	<b>Bit 1</b>	<b>Bit 0</b>	<b>Reset value: xxxxb</b>

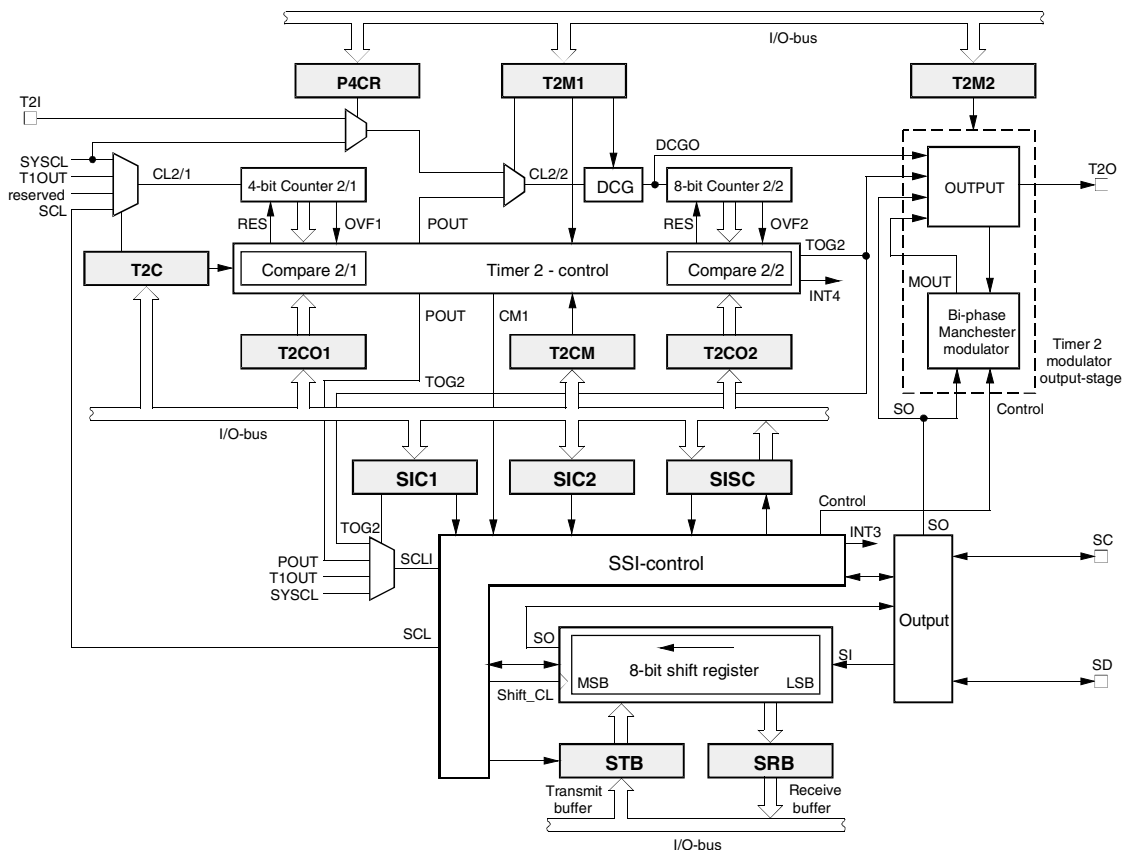

The SRB is the receive buffer of the SSI. The shift register clocks serial data in (most significant bit first) and loads the content into the receive buffer when a complete telegram has been received.

## Combination Modes

The UTCM consists of one timer (Timer 2) and a serial interface. There is a multitude of modes in which the timers and serial interface can work together.

The 8-bit wide serial interface operates as shift register for modulation. The modulator units work together with the timers and shift the data bits into or out of the shift register.

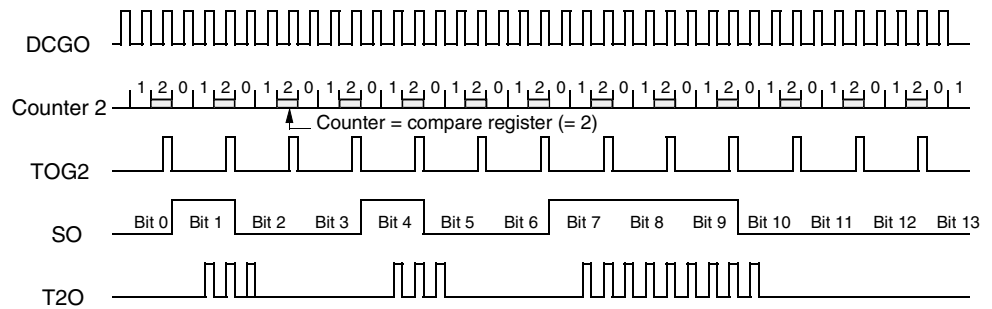

**Figure 52.** Combination Timer 2 and SSI

### Combination Mode 1: Burst Modulation

- SSI mode 1: 8-bit NRZ and internal data SO output to the Timer 2 modulator stage
- Timer 2 mode 1, 2, 3 or 4: 8-bit compare counter with 4-bit programmable prescaler and DCG
- Timer 2 output mode 3: Duty cycle burst generator

**Figure 53.** Carrier Frequency Burst Modulation with the SSI Internal Data Output

### Combination mode 2: Bi-phase modulation 1

- SSI mode 1: 8-bit shift register internal data output (SO) to the Timer 2 modulator stage
- Timer 2 mode 1, 2, 3 or 4: 8-bit compare counter with 4-bit programmable prescaler
- Timer 2 output mode 4: Modulator 2 of Timer 2 modulates the SSI internal data output to Bi-phase code

**Figure 54.** Bi-phase Modulation 1

### Combination Mode 3: Manchester Modulation 1

SSI mode 1: 8-bit shift register internal data output (SO) to Timer 2 modulator stage

Timer 2 mode 1, 2, 3 or 4: 8-bit compare counter with 4-bit programmable prescaler

Timer 2 output mode 5: Modulator 2 of Timer 2 modulates the SSI internal data output to Manchester code

**Figure 55. Manchester Modulation 1**

### Combination Mode 4: Manchester Modulation 2

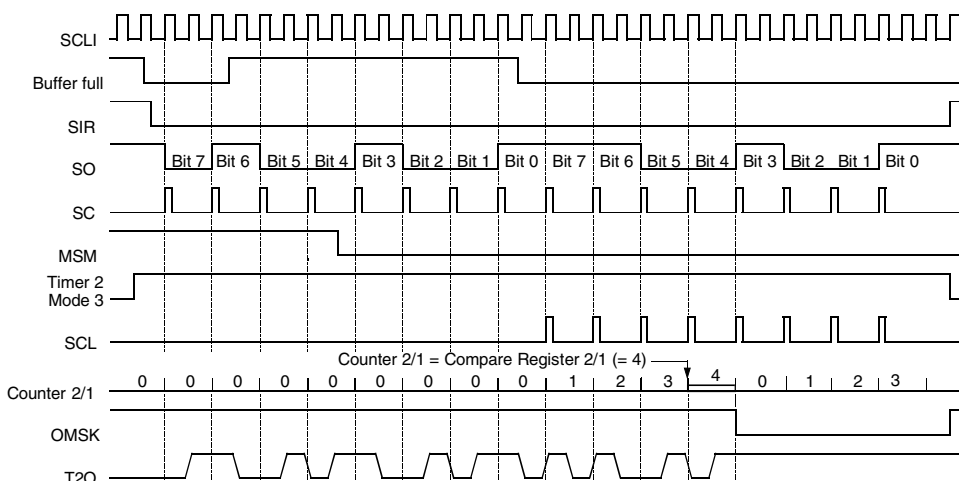

SSI mode 1: 8-bit shift register internal data output (SO) to Timer 2 modulator stage

Timer 2 mode 3: 8-bit compare counter and 4-bit prescaler

Timer 2 output mode 5: Modulator 2 of Timer 2 modulates the SSI data output to Manchester code

The 4-bit stage can be used as prescaler for the SSI to generate the stop signal for Modulator 2. The SSI has a special mode to supply the prescaler with the shift-clock. The control output signal (OMSK) of the SSI is used as a stop signal for the modulator. Figure 56 is an example for a 12-bit Manchester telegram.

**Figure 56. Manchester Modulation 2**

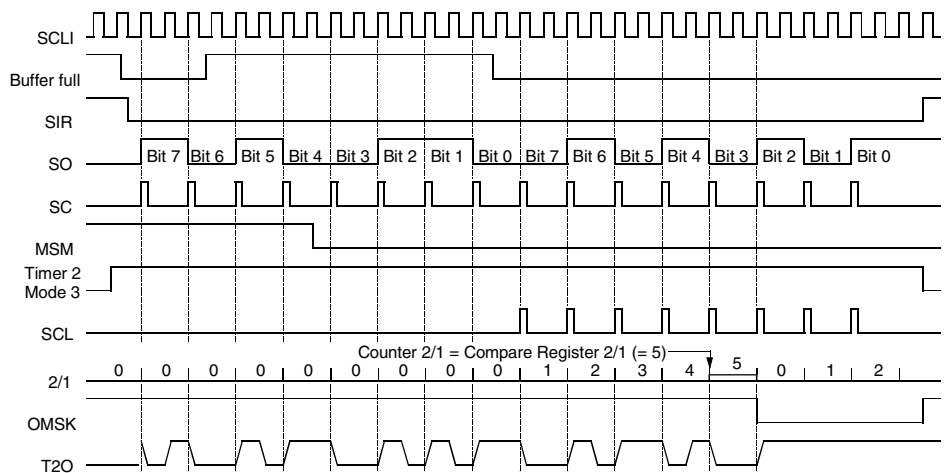

## Combination Mode 5: Bi-phase Modulation 2

- SSI mode 1: 8-bit shift register internal data output (SO) to the Timer 2 modulator stage
- Timer 2 mode 3: 8-bit compare counter and 4-bit prescaler
- Timer 2 output mode 4: Modulator 2 of Timer 2 modulates the SSI data output to Bi-phase code

The 4-bit stage can be used as prescaler for the SSI to generate the stop signal for Modulator 2. The SSI has a special mode to supply the prescaler via the shift-clock. The control output signal (OMSK) of the SSI is used as a stop signal for the modulator. Figure 57 is an example for a 13-bit Bi-phase telegram.

**Figure 57.** Bi-phase Modulation 2

## Absolute Maximum Ratings

Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

All inputs and outputs are protected against high electrostatic voltages or electric fields. However, precautions to minimize the build-up of electrostatic charges during handling are recommended. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (e.g.,  $V_{DD}$ ).

Parameters	Symbol	Value	Unit
Supply voltage	$V_{DD}$	-0.3 to +6.5	V
Input voltage (on any pin)	$V_{IN}$	$V_{SS} - 0.3 \leq V_{IN} \leq V_{DD} + 0.3$	V
Output short circuit duration	$t_{short}$	Indefinite	s
Operating temperature range	$T_{amb}$	-40 to +125	°C
Storage temperature range	$T_{stg}$	-40 to +130	°C
Thermal resistance (SSO20)	$R_{thJA}$	140	K/W
Soldering temperature ( $t \leq 10$ s)	$T_{sld}$	260	°C

## Electrical Characteristics – DC Operating

$V_{SS} = 0\text{ V}$ ,  $T_{amb} = -40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  unless otherwise specified

Parameters	Test Conditions	Symbol	Min.	Typ.	Max.	Unit
<b>Power Supply</b>						
Operating voltage at $V_{DD}$		$V_{DD}$	$V_{POR}$		6.5	V
Active current CPU active	$f_{SYSCL} = 1\text{ MHz}$ $V_{DD} = 1.8\text{ V}$ $V_{DD} = 3.0\text{ V}$ $V_{DD} = 6.5\text{ V}$	$I_{DD}$		120 200 500	350	$\mu\text{A}$ $\mu\text{A}$ $\mu\text{A}$

## Emulation

The basic function of emulation is to test and evaluate the customer's program and hardware in real time. This therefore enables the analysis of any timing, hardware or software problem. For emulation purposes, all MARC4 controllers include a special emulation mode. In this mode, the internal CPU core is inactive and the I/O buses are available via Port 0 and Port 1 to allow an external access to the on-chip peripherals. The MARC4 emulator uses this mode to control the peripherals of any MARC4 controller (target chip) and emulates the lost ports for the application.

The MARC4 emulator can stop and restart a program at specified points during execution, making it possible for the applications engineer to view the memory contents and those of various registers during program execution. The designer also gains the ability to analyze the executed instruction sequences and all the I/O activities.

**Figure 78.** MARC4 Emulation

## Option Settings for Ordering

- Notes:
1. It is required to select an output option for each port pin (Port 2, Port 4, Port 5).
  2. Don't use external components at BP20 that pull to  $V_{SS}$  during reset representing a resistor < 150k.

## Ordering Information

Extended Type Number <sup>(1)</sup>	Program Memory	Data-EEPROM	Package	Delivery
ATAR080x-yyy-TKQYz	2 kB ROM	No	SSO20	Taped and reeled
ATAR080x-yyy-TKSYz	2 kB ROM	No	SSO20	Tubes

Note: 1. x = Hardware revision  
 yyy = Customer specific ROM-version  
 z = Operating temperature range: D = -40°C to +125°C  
 Y = Lead-free

## Package Information

### Package SSO20

Dimensions in mm

technical drawings  
 according to DIN  
 specifications

## Revision History

Please note that the referring page numbers in this section are referred to the specific revision mentioned, not to this document.

### Changes from Rev. 4676A - 02/03 to Rev. 4676B - 12/03

1. Put datasheet in a new template.
2. Figure 5 “RAM Map” on page 5 changed.
3. Table 9 “Peripheral Addresses” on page 21 changed.
4. New heading rows at Table “Absolute Maximum Ratings” on page 54 added.
5. Section “Emulation” on page 58 added.
6. Table “Ordering Information” on page 60 added.
7. Table name on page 59 changed.

### Changes from Rev. 4676B - 12/03 to Rev. 4676C - 02/04

1. Figure 4 on page 4 changed.
2. Figure 59 to Figure 77 on page 58 to page 64 added.
3. “Ordering Information” on page 66 changed.

### Changes from Rev. 4676C - 02/04 to Rev. 4676D - 12/04

1. Put datasheet in a new template.
2. Lead-free Logo on page 1 added.
3. Section “ROM” on page 4 changed.
4. Section “Interrupt processing” on page 8 changed.
5. Section “4-MHz” Oscillator on pages 16-17 changed.
6. Section “32-kHz Oscillator” on page 17 changed.
7. Section “Timer 2” on page 30 changed.
8. Table 18 “Timer 2 Output Select Bits” on page 39 changed.
9. “Option Settings for Ordering” on page 65 changed.
10. “Ordering Information” on page 66 changed.
