

50-A, 4.5-V to 14-V INPUT, NON-ISOLATED, WIDE-OUTPUT, ADJUSTABLE POWER MODULE WITH *TurboTrans*[™]

Check for Samples: [PTH08T250W](#)

FEATURES

- Up to 50-A Output Current
- 4.5-V to 14-V Input Voltage
- Wide-Output Voltage Adjust (0.7 V to 3.6 V)
- $\pm 1.5\%$ Total Output Voltage Variation
- Efficiencies up to 96%
- Output Overcurrent Protection (Nonlatching, Auto-Reset)
- Operating Temperature: -40°C to 85°C
- Safety Agency Approvals:
 - UL/IEC/CSA-C22.2 60950-1
- Prebias Startup
- On/Off Inhibit
- Differential Output Voltage Remote Sense
- Adjustable Undervoltage Lockout
- Auto-Track[™] Sequencing
- Multi-Phase, Switch-Mode Topology

- TurboTrans[™] Technology
- Designed to meet Ultra-Fast Transient Requirements up to 300 A/ μs
- SmartSync Technology
- Parallel Operation
- POLA[™] Compatible

APPLICATIONS

- Complex Multi-Voltage Systems
- Servers
- Workstations

DESCRIPTION

The PTH08T250W is a high-performance 50-A rated, non-isolated power module. This module represents the 2nd generation of the popular PTH series power modules with a reduced footprint and improved features.

Operating from an input voltage range of 4.5 V to 14 V, the PTH08T250W requires a single resistor to set the output voltage to any value over the range, 0.7 V to 3.6 V. The wide input voltage range makes the PTH08T250W particularly suitable for advanced computing and server applications that utilize a loosely regulated 8-V to 12-V intermediate distribution bus. Additionally, the wide input voltage range increases design flexibility by supporting operation with tightly regulated 5-V, 8-V, or 12-V intermediate bus architectures.

The module incorporates a comprehensive list of features. Output overcurrent and over-temperature shutdown protects against most load faults. A differential remote sense ensures tight load regulation. An adjustable under-voltage lockout allows the turn-on voltage threshold to be customized. Auto-Track[™] sequencing is a popular feature that greatly simplifies the simultaneous power-up and power-down of multiple modules in a power system. Additionally, the capability to current share between multiple PTH08T250W modules allows for load currents greater than 50 A on a single rail.

The PTH08T250W includes new patent pending technologies, **TurboTrans**[™] and **SmartSync**. The TurboTrans feature optimizes the transient response of the regulator while simultaneously reducing the quantity of external output capacitors required to meet a target voltage deviation specification. Additionally, for a target output capacitor bank, TurboTrans can be used to significantly improve the regulators transient response by reducing the peak voltage deviation. SmartSync allows for switching frequency synchronization of multiple modules, thus simplifying EMI noise suppression tasks and reducing input capacitor RMS current requirements.

Double-sided surface mount construction provides a low profile and compact footprint. Package options include both through-hole and surface mount configurations that are lead (Pb) - free and RoHS compatible.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

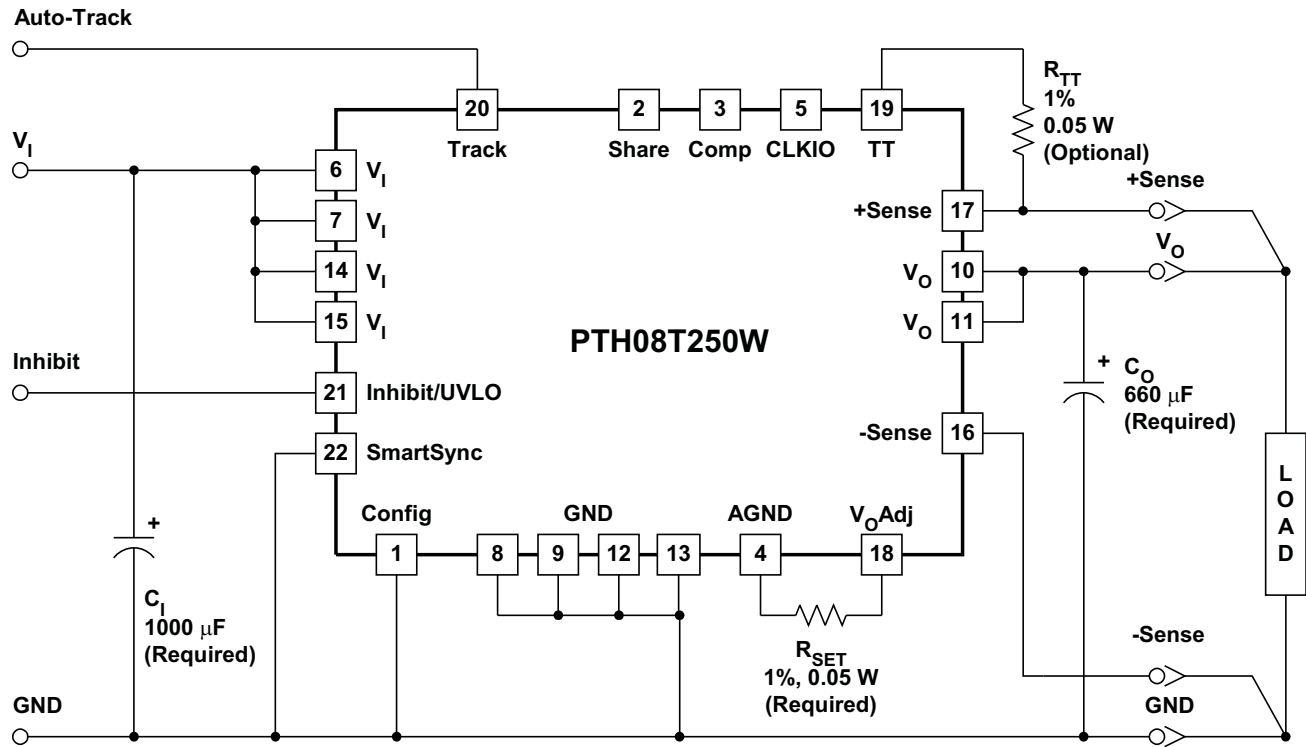

TurboTrans, Auto-Track, TMS320 are trademarks of Texas Instruments.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

STANDARD APPLICATION

UDG-07002

- A. When operating at an input voltage greater than 8V the minimum required input capacitance may be reduced to 560µF.

ORDERING INFORMATION

For the most current package and ordering information, see the Package Option Addendum at the end of this datasheet, or see the TI website at www.ti.com.

	SYNC High-Level Input Voltage		2.0		5.5	V
	SYNC Low-Level Input Voltage				0.8	V
	SYNC Minimum Pulse Width		200			nSec

- (1) For output voltages less than 1.2 V, the output ripple may increase (up to 2x) when operating at input voltages greater than ($V_O \times 12$). Adjusting the switching frequency using the SmartSync feature may increase or decrease this ratio. Please review the SmartSync section of the Application Information for further guidance.
- (2) The set-point voltage tolerance is affected by the tolerance and stability of R_{SET} . The stated limit is unconditionally met if R_{SET} has a tolerance of 1% with 100 ppm/°C or better temperature stability.
- (3) A low-leakage (<100 nA), open-drain device, such as MOSFET or voltage supervisor IC, is recommended to control pin 20. The open-circuit voltage is less than 8 V_{dc} .
- (4) Do not place an external pull-up on this pin. If it is left open-circuit, the module operates when input power is applied. A small, low-leakage (<100 nA) MOSFET is recommended for control. For additional information, see the related application section.
- (5) The PTH08T250W is a two-phase power module. Each phase switches at 300 kHz typical, 180° out of phase from one another. The over-all switching frequency is 600 kHz typical. SmartSync controls the frequency of an individual phase. When using SmartSync the external synchronization frequency must be present before a valid input voltage is present, or before the release of inhibit control.

- (6) A 1000 μF electrolytic input capacitor is required for proper operation. When operating at an input voltage greater than 8V the minimum required input capacitance may be reduced to 560 μF . The input capacitor must be rated for a minimum of 600 mA rms of ripple current.
- (7) 660 μF of external **non-ceramic** output capacitance is required for basic operation. Adding additional capacitance at the load further improves transient response. See the Capacitor Application Information section and the TurboTrans Technology section for more guidance.
- (8) This is the calculated maximum when not using *TurboTrans™* technology. This value includes both ceramic and non-ceramic capacitors. The minimum ESR requirement often results in a lower value of output capacitance. See the Capacitor Application Information section for more guidance.
- (9) Ceramic output capacitance may be added in addition to the required non-ceramic output capacitance. The amount of ceramic capacitance must be less than the non-ceramic capacitance, not to exceed 1000 μF .
- (10) When using *TurboTrans™* technology, a minimum value of output capacitance is required for proper operation. Additionally, low ESR capacitors are required for proper operation. See the TurboTrans Technology section for further guidance.

TERMINAL FUNCTIONS

TERMINAL		DESCRIPTION
NAME	NO.	
V_I	6,7,14,15	The positive input voltage power node to the module, which is referenced to common GND.
V_O	10,11	The regulated positive power output with respect to GND.
GND	8,9,12,13	This is the common ground connection for the V_I and V_O power connections. It is also the 0 V_{dc} reference for the control inputs.
Inhibit ⁽¹⁾ and UVLO	21	<p>The Inhibit pin is an open-collector/drain, negative logic input that is referenced to GND. Applying a low level ground signal to this input disables the module's output and turns off the output voltage. When the Inhibit control is active, the input current drawn by the regulator is significantly reduced. If the Inhibit pin is left open-circuit, the module produces an output whenever a valid input source is applied.</p> <p>This pin is also used for input undervoltage lockout (UVLO) programming. Connecting a resistor from this pin to GND (pin 13) allows the ON threshold of the UVLO to be adjusted higher than the default value. For more information, see the Application Information section.</p>
V_O Adjust	18	<p>A 0.05 W 1% resistor must be directly connected between this pin and pin 4 (AGND) to set the output voltage to a value higher than 0.7 V. The temperature stability of the resistor should be 100 ppm/°C (or better). The setpoint range for the output voltage is from 0.7 V to 3.6 V. If left open circuit, the output voltage defaults to its lowest value. For further information, on output voltage adjustment see the related application note.</p> <p>The specification table gives the preferred resistor values for a number of standard output voltages.</p>
+ Sense	17	The sense input allows the regulation circuit to compensate for voltage drop between the module and the load. The +Sense pin should always be connected to V_O , either at the load for optimal voltage accuracy, or at the module (pin 11).
– Sense	16	The sense input allows the regulation circuit to compensate for voltage drop between the module and the load. The –Sense pin should always be connected to GND, either at the load for optimal voltage accuracy, or at the module (pin 13).
Track	20	<p>This is an analog control input that enables the output voltage to follow an external voltage. This pin becomes active typically 25 ms after a valid input voltage has been applied, and allows direct control of the output voltage from 0 V up to the nominal set-point voltage. Within this range the module's output voltage follows the voltage at the Track pin on a volt-for-volt basis. When the control voltage is raised above this range, the module regulates at its set-point voltage. The feature allows the output voltage to rise simultaneously with other modules powered from the same input bus. If unused, this input should be connected to V_I.</p> <p>NOTE: Due to the undervoltage lockout feature, the output of the module cannot follow its own input voltage during power up. For more information, see the related application note.</p>
TurboTrans™	19	This input pin adjusts the transient response of the regulator. To activate the TurboTrans™ feature, a 1%, 50 mW resistor, must be connected between this pin and pin 17 (+Sense) very close to the module. For a given value of output capacitance, a reduction in peak output voltage deviation is achieved by utilizing this feature. If unused, this pin must be left open-circuit. The resistance requirement can be selected from the TurboTrans resistor table in the Application Information section. External capacitance must never be connected to this pin unless the TurboTrans resistor value is a short, 0Ω.
SmartSync	22	This input pin synchronizes the switching frequency of the module to an external clock frequency. The SmartSync feature can be used to synchronize the switching frequency of multiple modules, aiding EMI noise suppression efforts. The external synchronization frequency must be present before a valid input voltage is present, or before the release of inhibit control. If unused, this pin MUST be connected to GND. For more information, please review the Application Information section.
CONFIG	1	When two modules are connected together to share load current one must be configured as the MASTER and the other as the SLAVE. This pin is used to configure the module as either MASTER or SLAVE. To configure the module as the MASTER, connect this pin to GND. To configure the module as the SLAVE, connect this pin to V_I (pin 6). When not sharing current, this pin should be connected to GND.
Share	2	This pin is used when connecting two modules together to share load current. When two modules are sharing current the Share pin of both modules must be connected together. When not sharing current, this pin MUST be left open (floating).
Comp	3	This pin is used when connecting two modules together to share load current. When two modules are sharing current the Comp pin of both modules must be connected together. When not sharing current, this pin MUST be left open (floating).
AGND	4	This pin is the internal analog ground of the module. This pin provides the return path for the V_O Adjust resistor (R_{SET}). When two modules are sharing current the AGND pin of both modules must be connected together. Also, when two modules are connected, R_{SET} must be connected only on the MASTER module.
CLKIO	5	This pin is used when connecting two modules together to share load current. When two modules are sharing current the CLKIO pin of both modules must be connected together. When not sharing current, this pin MUST be left open (floating).

APPLICATION INFORMATION

ADJUSTING THE OUTPUT VOLTAGE

The V_O Adjust control sets the output voltage of the PTH08T250W. The adjustment range of the PTH08T250W is 0.7 V to 3.6 V. The adjustment method requires the addition of a single external resistor, R_{SET} , that must be connected directly between pins V_O Adjust (pin 18) and AGND (pin 4). Table 1 gives the standard value of the external resistor for a number of standard voltages, along with the actual output voltage that this resistance value provides.

For other output voltages, the value of the required resistor can either be calculated using the following formula, or simply selected from the range of values given in Table 2. Figure 11 shows the placement of the required resistor.

$$R_{SET} = 30.1 \text{ (k}\Omega\text{)} \times \left(\frac{0.7}{V_O - 0.7} \right) - 6.49 \text{ (k}\Omega\text{)} \quad (1)$$

Table 1. Standard Values of R_{SET} for Standard Output Voltages

V_O (Standard) (V)	R_{SET} (Standard Value) (k Ω)	V_O (Actual) (V)
3.3	1.62	3.298
2.5	5.23	2.498
2.0	9.76	1.997
1.8	12.7	1.798
1.5	19.6	1.508
1.2	35.7	1.199
1.0 ⁽¹⁾	63.4	1.001
0.7 ⁽¹⁾	Open	0.700

- (1) The maximum input voltage is duty cycle limited to $(V_O \times 12)$ or 14 volts, whichever is less. The maximum allowable input voltage is a function of switching frequency, and may increase or decrease when the SmartSync feature is utilized. Please review the SmartSync section of the Application Information for further guidance.

- (1) R_{SET} : Use a 0.05 W resistor with a tolerance of 1% and temperature stability of 100 ppm/ $^{\circ}$ C (or better). Connect the resistor directly between pins 18 and 4, as close to the regulator as possible, using dedicated PCB traces.
- (2) Never connect capacitors from V_O Adjust to either + Sense, GND, or V_O . Any capacitance added to the V_O Adjust pin affects the stability of the regulator.

Figure 11. V_O Adjust Resistor Placement

CAPACITOR RECOMMENDATIONS FOR THE PTH08T250W POWER MODULE

Capacitor Technologies

Electrolytic Capacitors

When using electrolytic capacitors, high quality, computer-grade electrolytic capacitors are recommended. Aluminum electrolytic capacitors provide adequate decoupling over the frequency range, 2 kHz to 150 kHz, and are suitable when ambient temperatures are above -20°C. For operation below -20°C, tantalum, ceramic, or OS-CON type capacitors are required.

Ceramic Capacitors

Above 150 kHz the performance of aluminum electrolytic capacitors is less effective. Multilayer ceramic capacitors have very low ESR and a resonant frequency higher than the bandwidth of the regulator. They can be used to reduce the reflected ripple current at the input as well as improve the transient response of the output.

Tantalum, Polymer-Tantalum Capacitors

Tantalum type capacitors may only be used on the output bus, and are recommended for applications where the ambient operating temperature is less than 0°C. The AVX TPS series and Kemet capacitor series are suggested over many other tantalum types due to their lower ESR, higher rated surge, power dissipation, and ripple current capability. Tantalum capacitors that have no stated ESR or surge current rating are not recommended for power applications.

Input Capacitor (Required)

The PTH08T250W requires a minimum input capacitance of 1000 μ F. The ripple current rating of the input capacitor must be at least 600 mArms. An optional 22 μ F X5R/X7R ceramic capacitor is recommended to reduce RMS ripple current.

Input Capacitor Information

The size and value of the input capacitor is determined by the converter's transient performance capability. This minimum value assumes that the converter is supplied with a responsive, low inductance input source. This source should have ample capacitive decoupling, and be distributed to the converter via PCB power and ground planes.

Ceramic capacitors should be located as close as possible to the module's input pins, within 0.5 inch (1,3 cm). Adding ceramic capacitance is necessary to reduce the high-frequency ripple voltage at the module's input. This reduces the magnitude of the ripple current through the electrolytic capacitor, as well as the amount of ripple current reflected back to the input source. Additional ceramic capacitors can be added to further reduce the RMS ripple current requirement for the electrolytic capacitor.

The main considerations when selecting input capacitors are the RMS ripple current rating, temperature stability, and less than 100 m Ω of equivalent series resistance (ESR).

Regular tantalum capacitors are not recommended for the input bus. These capacitors require a recommended minimum voltage rating of 2 \times (maximum dc voltage + ac ripple). This is standard practice to ensure reliability. No tantalum capacitors were found with a sufficient voltage rating to meet this requirement.

When the operating temperature is below 0°C, the ESR of aluminum electrolytic capacitors increases. For these applications, OS-CON, poly-aluminum, and polymer-tantalum types should be considered.

Output Capacitor (Required)

The PTH08T250W requires a minimum output capacitance of 660 μF of polymer-aluminum, tantalum, or polymer-tantalum type. Ceramic capacitors may be used in addition to the required bulk capacitance.

The required capacitance above the minimum is determined by actual transient deviation requirements. See the TurboTrans Technology application section within this document for specific capacitance selection.

Output Capacitor Information

When selecting output capacitors, the main considerations are capacitor type, temperature stability, and ESR. When using the TurboTrans feature, the capacitance \times ESR product should also be considered (see the following section).

Ceramic output capacitors added for high-frequency bypassing should be located as close as possible to the load to be effective. Ceramic capacitor values below 10 μF should not be included when calculating the total output capacitance value.

When the operating temperature is below 0°C, the ESR of aluminum electrolytic capacitors increases. For these applications, OS-CON, poly-aluminum, and polymer-tantalum types should be considered.

TurboTrans Output Capacitance

TurboTrans allows the designer to optimize the output capacitance according to the system transient design requirement. High quality, ultra-low ESR capacitors are required to maximize TurboTrans effectiveness. When using TurboTrans, the capacitor's capacitance (μF) \times ESR ($\text{m}\Omega$) product determines its capacitor type; Type A, B, or C. These three types are defined as follows:

Type A = ($100 \leq \text{capacitance} \times \text{ESR} \leq 1000$) (e.g. ceramic) (may be used in addition to Type B or Type C capacitors)

Type B = ($1000 < \text{capacitance} \times \text{ESR} \leq 5000$) (e.g. polymer-tantalum)

Type C = ($5000 < \text{capacitance} \times \text{ESR} \leq 10,000$) (e.g. OS-CON)

When using more than one type of output capacitor, select the capacitor type that makes up the majority of your total output capacitance. When calculating the $C \times \text{ESR}$ product, use the maximum ESR value from the capacitor manufacturer's datasheet.

Working Examples:

A capacitor with a capacitance of 330 μF and an ESR of 5 $\text{m}\Omega$, has a $C \times \text{ESR}$ product of 1650 $\mu\text{F} \times \text{m}\Omega$ ($330 \mu\text{F} \times 5 \text{m}\Omega$). This is a Type B capacitor. A capacitor with a capacitance of 1000 μF and an ESR of 8 $\text{m}\Omega$, has a $C \times \text{ESR}$ product of 8000 $\mu\text{F} \times \text{m}\Omega$ ($1000 \mu\text{F} \times 8 \text{m}\Omega$). This is a Type C capacitor.

See the TurboTrans Technology application section within this document for specific capacitance selection.

[Table 3](#) includes a preferred list of capacitors by type and vendor. See the Output Bus / TurboTrans column.

Non-TurboTrans Output Capacitance

If the TurboTrans feature is not used, minimum ESR and maximum capacitor limits must be followed. System stability may be effected and increased output capacitance may be required without TurboTrans.

When using the PTH08T250W, observe the minimum ESR of the entire output capacitor bank. The minimum ESR limit of the output capacitor bank is 7 $\text{m}\Omega$. A list of preferred low-ESR type capacitors, are identified in [Table 3](#).

When using the PTH08T250W without the TurboTrans feature, the maximum amount of capacitance is 1000 μF of ceramic type. Large amounts of capacitance may reduce system stability.

Utilizing the TurboTrans feature improves system stability, improves transient response, and reduces the amount of output capacitance required to meet system transient design requirements.

Designing for Fast Load Transients

The transient response of the dc/dc converter has been characterized using a load transient with a di/dt of 2.5 A/μs. The typical voltage deviation for this load transient is given in the Electrical Characteristics table using the minimum required value of output capacitance. As the di/dt of a transient is increased, the response of a converter's regulation circuit ultimately depends on its output capacitor decoupling network. This is an inherent limitation with any dc/dc converter once the speed of the transient exceeds its bandwidth capability.

If the target application specifies a higher di/dt or lower voltage deviation, the requirement can only be met with additional low ESR ceramic capacitor decoupling. Generally, with load steps greater than 100 A/μs, adding multiple 10 μF ceramic capacitors plus 10 × 1 μF, and numerous high frequency ceramics (≤ 0.1 μF) is all that is required to soften the transient higher frequency edges. The PCB location of these capacitors in relation to the load is critical. DSP, FPGA and ASIC vendors identify types, location and amount of capacitance required for optimum performance. Low impedance buses, unbroken PCB copper planes, and components located as close as possible to the high frequency devices are essential for optimizing transient performance.

Capacitor Table

Table 3 identifies the characteristics of acceptable capacitors from a number of vendors. The recommended number of capacitors required at both the input and output buses is identified for each capacitor.

This is not an extensive capacitor list. Capacitors from other vendors are available with comparable specifications. Those listed are for guidance. The RMS ripple current rating and ESR (at 100 kHz) are critical parameters necessary to ensure both optimum regulator performance and long capacitor life.

(1) Capacitor Supplier Verification

Please verify availability of capacitors identified in this table. Capacitor suppliers may recommend alternative part numbers because of limited availability or obsolete products. In some instances, the capacitor product life cycle may be in decline and have short-term consideration for obsolescence.

RoHS, Lead-free and Material Details

See the capacitor suppliers regarding material composition, RoHS status, lead-free status, and manufacturing process requirements. Component designators or part number deviations can occur when material composition or soldering requirements are updated.

(2) Required capacitors with TurboTrans. See the TransTrans Application information for Capacitor Selection

Capacitor Type Groups by ESR (Equivalent Series Resistance) :

- (a) Type A = (100 < capacitance × ESR ≤ 1000)
- (b) Type B = (1,000 < capacitance × ESR ≤ 5,000)
- (c) Type C = (5,000 < capacitance × ESR ≤ 10,000)

- (3) Total bulk nonceramic capacitors on the output bus with ESR of ≥ 15mΩ to ≤ 30mΩ requires an additional ≥ 200 μF of ceramic capacitor.
- (4) Aluminum Electrolytic capacitor not recommended for the TurboTrans due to higher ESR × capacitance products. Aluminum and higher ESR capacitors can be used in conjunction with lower ESR capacitance.
- (5) Output bulk capacitor's maximum ESR is ≥ 30 mΩ. Additional ceramic capacitance of ≥ 200 μF is required.
- (6) N/R – Not recommended. The voltage rating does not meet the minimum operating limits.

- (7) Total bulk nonceramic capacitors on the output bus with ESR of ≥ 15mΩ to ≤ 30mΩ requires an additional ≥ 200 µF of ceramic capacitor.
- (8) Aluminum Electrolytic capacitor not recommended for the TurboTrans due to higher ESR x capacitance products. Aluminum and higher ESR capacitors can be used in conjunction with lower ESR capacitance.
- (9) N/R – Not recommended. The voltage rating does not meet the minimum operating limits.
- (10) Required capacitors with TurboTrans. See the TransTrans Application information for Capacitor Selection Capacitor Type Groups by ESR (Equivalent Series Resistance) :
 - (a) Type A = (100 < capacitance x ESR ≤ 1000)
 - (b) Type B = (1,000 < capacitance x ESR ≤ 5,000)
 - (c) Type C = (5,000 < capacitance x ESR ≤ 10,000)
- (11) The voltage rating of this capacitor only allows it to be used for output voltage that is equal to or less than 80% of the working voltage.
- (12) Maximum ceramic capacitance on the output bus is ≤ tbd µF. Any combination of the ceramic capacitor values is limited to tbd µF for non-TurboTrans applications. The total capacitance is limited to tbd µF which includes all ceramic and non-ceramic types.

TurboTrans™ Technology

TurboTrans technology is a feature introduced in the T2 generation of the PTH/PTV family of power modules. TurboTrans optimizes the transient response of the regulator with added external capacitance using a single external resistor. Benefits of this technology include reduced output capacitance, minimized output voltage deviation following a load transient, and enhanced stability when using ultra-low ESR output capacitors. The amount of output capacitance required to meet a target output voltage deviation is reduced with TurboTrans activated. Likewise, for a given amount of output capacitance, with TurboTrans engaged, the amplitude of the voltage deviation following a load transient is reduced. Applications requiring tight transient voltage tolerances and minimized capacitor footprint area benefits greatly from this technology.

TurboTrans™ Selection

Utilizing TurboTrans requires connecting a resistor, R_{TT} , between the +Sense pin (pin 17) and the TurboTrans pin (pin 19). The value of the resistor directly corresponds to the amount of output capacitance required. All T2 products require a minimum value of output capacitance whether or not TurboTrans is utilized. For the PTH08T250W, the minimum required capacitance is 1000 μF . When using TurboTrans, capacitors with a capacitance \times ESR product below 10,000 $\mu\text{F}\times\text{m}\Omega$ are required. (Multiply the capacitance (in μF) by the ESR (in $\text{m}\Omega$) to determine the capacitance \times ESR product.) See the Capacitor Selection section of the datasheet for a variety of capacitors that meet this criteria.

Figure 12 thru Figure 15 show the amount of output capacitance required to meet a desired transient voltage deviation with and without TurboTrans for several capacitor types; Type B (e.g. polymer-tantalum) and Type C (e.g. OS-CON). To calculate the proper value of R_{TT} , first determine your required transient voltage deviation limits and magnitude of your transient load step. Next, determine what type of output capacitors to be used. (If more than one type of output capacitor is used, select the capacitor type that makes up the majority of your total output capacitance.) Knowing this information, use the chart in Figure 12 thru Figure 15 that corresponds to the capacitor type selected. To use the chart, begin by dividing the maximum voltage deviation limit (in mV) by the magnitude of your load step (in Amps). This gives a mV/A value. Find this value on the Y-axis of the appropriate chart. Read across the graph to the 'With TurboTrans' plot. From this point, read down to the X-axis which lists the minimum required capacitance, C_O , to meet that transient voltage deviation. The required R_{TT} resistor value can then be calculated using the equation or selected from the TurboTrans table. The TurboTrans tables include both the required output capacitance and the corresponding R_{TT} values to meet several values of transient voltage deviation for 25% (12.5 A), 50% (25 A), and 75% (37.5 A) output load steps.

The chart can also be used to determine the achievable transient voltage deviation for a given amount of output capacitance. Selecting the amount of output capacitance along the X-axis, reading up to the 'With TurboTrans' curve, and then over to the Y-axis, gives the transient voltage deviation limit for that value of output capacitance. The required R_{TT} resistor value can be calculated using the equation or selected from the TurboTrans table.

As an example, let's look at a 12-V application requiring a 60 mV deviation during an 15 A load transient. A majority of 470 μF , 10 $\text{m}\Omega$ output capacitors are used. Use the 12 V, Type B capacitor chart, Figure 12. Dividing 60 mV by 15 A gives 4 mV/A transient voltage deviation per amp of transient load step. Select 4 mV/A on the Y-axis and read across to the 'With TurboTrans' plot. Following this point down to the X-axis gives us a minimum required output capacitance of approximately 1500 μF . The required R_{TT} resistor value for 1500 μF can then be calculated or selected from Table 4. The required R_{TT} resistor is approximately 17.4 $\text{k}\Omega$.

To see the benefit of TurboTrans, follow the 4 mV/A marking across to the 'Without TurboTrans' plot. Following that point down shows that you would need a minimum of 7500 μF of output capacitance to meet the same transient deviation limit. This is the benefit of TurboTrans.

PTH08T250W Type B Capacitors

Figure 12. Capacitor Type B, $1000 < C(\mu\text{F}) \times \text{ESR}(\text{m}\Omega) \leq 5000$ (e.g. Polymer-Tantalum)

Figure 13. Capacitor Type B, $1000 < C(\mu\text{F}) \times \text{ESR}(\text{m}\Omega) \leq 5000$ (e.g. Polymer-Tantalum)

Table 4. Type B TurboTrans C_O Values and Required R_{TT} Selection Table

Transient Voltage Deviation (mV)			12 Volt Input		5 Volt Input

25	50	75	3100	0.649	4000	short

R_{TT} Resistor Selection

The TurboTrans resistor value, R_{TT} can be determined from the TurboTrans programming [Equation 2](#).

$$R_{TT} = 40 \times \frac{1 - (C_O/3300)}{(5 \times C_O/3300) - 1} \text{ (k}\Omega\text{)} \tag{2}$$

Where C_O is the total output capacitance in μF . C_O values greater than or equal to 3300 μF require R_{TT} to be a short, 0 Ω . ([Equation 2](#) results in a negative value for R_{TT} when $C_O > 3300 \mu\text{F}$.)

To ensure stability, a minimum amount of output capacitance is required for a given R_{TT} resistor value. The value of R_{TT} must be calculated using the minimum required output capacitance determined from [Figure 12](#) and [Figure 13](#).

PTH08T250W Type C Capacitors

Figure 14. Capacitor Type C, $5000 < C(\mu\text{F}) \times \text{ESR}(\text{m}\Omega) \leq 10,000$ (e.g. OS-CON)

Figure 15. Capacitor Type C, $5000 < C(\mu\text{F}) \times \text{ESR}(\text{m}\Omega) \leq 10,000$ (e.g. OS-CON)

Table 5. Type C TurboTrans C_O Values and Required R_{TT} Selection Table

Transient Voltage Deviation (mV)			12 Volt Input		5 Volt Input	
25% load step (12.5 A)	50% load step (25 A)	75% load step (37.5 A)	C_O Minimum Required Output Capacitance (μF)	R_{TT} Required TurboTrans Resistor ($\text{k}\Omega$)	C_O Minimum Required Output Capacitance (μF)	R_{TT} Required TurboTrans Resistor ($\text{k}\Omega$)

20	40	60	6000	short	-	-

R_{TT} Resistor Selection

The TurboTrans resistor value, R_{TT} can be determined from the TurboTrans programming [Equation 3](#).

$$R_{TT} = 40 \times \frac{1 - (C_O/3300)}{(5 \times C_O/3300) - 1} \text{ (k}\Omega\text{)} \tag{3}$$

Where C_O is the total output capacitance in μF . C_O values greater than or equal to 3300 μF require R_{TT} to be a short, 0Ω . ([Equation 3](#) results in a negative value for R_{TT} when $C_O > 3300 \mu\text{F}$). To ensure stability, a minimum amount of output capacitance is required for a given R_{TT} resistor value. The value of R_{TT} must be calculated using the minimum required output capacitance determined from [Figure 14](#) and [Figure 15](#).

Figure 16. Typical TurboTrans™ Application

Soft-Start Power Up

The Auto-Track feature allows the power-up of multiple PTH/PTV modules to be directly controlled from the Track pin. However in a stand-alone configuration, or when the Auto-Track feature is not being used, the Track pin should be directly connected to the input voltage, V_I (see Figure 17).

Figure 17. Defeating the Auto-Track Function

Figure 18. Power-Up Waveform

When the Track pin is connected to the input voltage the Auto-Track function is permanently disengaged. This allows the module to power up entirely under the control of its internal soft-start circuitry. When power up is under soft-start control, the output voltage rises to the set-point at a quicker and more linear rate.

From the moment a valid input voltage is applied, the soft-start control introduces a short time delay (typically 10 ms–15 ms) before allowing the output voltage to rise.

The output then progressively rises to the module's setpoint voltage. Figure 18 shows the soft-start power-up characteristic of the PTH08T250W operating from a 5-V input bus and configured for a 1.2-V output. The waveforms were measured with a 25-A constant current load and the Auto-Track feature disabled. The initial rise in input current when the input voltage first starts to rise is the charge current drawn by the input capacitors. Power-up is complete within 30 ms.

Differential Output Voltage Remote Sense

Differential remote sense improves the load regulation performance of the module by allowing it to compensate for any IR voltage drop between its output and the load in either the positive or return path. An IR drop is caused by the output current flowing through the small amount of pin and trace resistance. With the sense pins connected, the difference between the voltage measured directly between the V_O and GND pins, and that measured at the Sense pins, is the amount of IR drop being compensated by the regulator. This should be limited to a maximum of 0.3 V.

If the remote sense feature is not used at the load, connect +Sense (pin 17) to V_O (pin 11) and connect –Sense (pin 16) to the module GND (pin 13).

The remote sense feature is not designed to compensate for the forward drop of nonlinear or frequency dependent components that may be placed in series with the converter output. Examples include OR-ing diodes, filter inductors, ferrite beads, and fuses. When these components are enclosed by the remote sense connection they are effectively placed inside the regulation control loop, which can adversely affect the stability of the regulator.

On/Off Inhibit

For applications requiring output voltage on/off control, the PTH08T250W incorporates an Inhibit control pin. The inhibit feature can be used wherever there is a requirement for the output voltage from the regulator to be turned off. The power modules function normally when the Inhibit pin is left open-circuit, providing a regulated output whenever a valid source voltage is connected to V_I with respect to GND.

Figure 19 shows the typical application of the inhibit function. Note the discrete transistor (Q1). The Inhibit input has its own internal pull-up. An external pull-up resistor should never be used with the inhibit pin. The input is not compatible with TTL logic devices. An open-collector (or open-drain) discrete transistor is recommended for control.

Turning Q1 on applies a low voltage to the Inhibit control pin and disables the output of the module. If Q1 is then turned off, the module executes a soft-start power-up sequence. A regulated output voltage is produced within 20 ms. Figure 20 shows the typical rise in both the output voltage and input current, following the turn-off of Q1. The turn off of Q1 corresponds to the rise in the waveform, V_{INH} . The waveforms were measured with a 25-A constant current load.

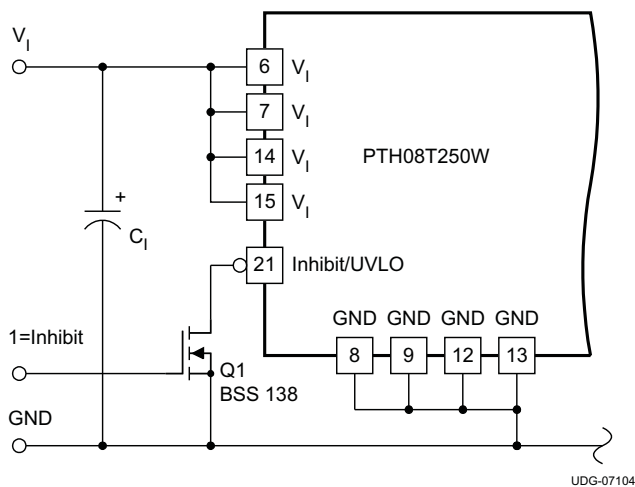

Figure 19. On/Off Inhibit Control Circuit

Figure 20. Power-Up Response from Inhibit Control

Overcurrent Protection

For protection against load faults, all modules incorporate output overcurrent protection. Applying a load that exceeds the regulator's overcurrent threshold causes the regulated output to shut down. Following shutdown, the module periodically attempts to recover by initiating a soft-start power-up. This is described as a *hiccup* mode of operation, whereby the module continues in a cycle of successive shutdown and power up until the load fault is removed. During this period, the average current flowing into the fault is significantly reduced. Once the fault is removed, the module automatically recovers and returns to normal operation.

Overtemperature Protection (OTP)

A thermal shutdown mechanism protects the module's internal circuitry against excessively high temperatures. A rise in the internal temperature may be the result of a drop in airflow, or a high ambient temperature. If the internal temperature exceeds the OTP threshold, the module's Inhibit control is internally pulled low. This turns the output off. The output voltage drops as the external output capacitors are discharged by the load circuit. The recovery is automatic, and begins with a soft-start power up. It occurs when the sensed temperature decreases by about 10°C below the trip point.

The overtemperature protection is a last resort mechanism to prevent thermal stress to the regulator. Operation at or close to the thermal shutdown temperature is not recommended and reduces the long-term reliability of the module. Always operate the regulator within the specified safe operating area (SOA) limits for the worst-case conditions of ambient temperature and airflow.

Smart Sync

Smart Sync is a feature that allows multiple power modules to be synchronized to a common frequency. When not used, this pin must be connect to GND. Driving the Smart Sync pins with an external oscillator set to the desired frequency, synchronizes all connected modules to the selected frequency. The synchronization frequency can be higher or lower than the nominal switching frequency of the modules within the range of 240 kHz to 400 kHz.

Synchronizing modules powered from the same bus eliminates beat frequencies reflected back to the input supply, and also reduces EMI filtering requirements. Eliminating the low beat frequencies (usually <10 kHz) allows the EMI filter to be designed to attenuate only the synchronization frequency. Power modules can also be synchronized out of phase to minimize ripple current and reduce input capacitance requirements.

The PTH08T250W requires that the external synchronization frequency be present before a valid input voltage is present or before release of the inhibit control. Figure 21 shows a standard circuit with two modules synchronized 180° out of phase using a D flip-flop.

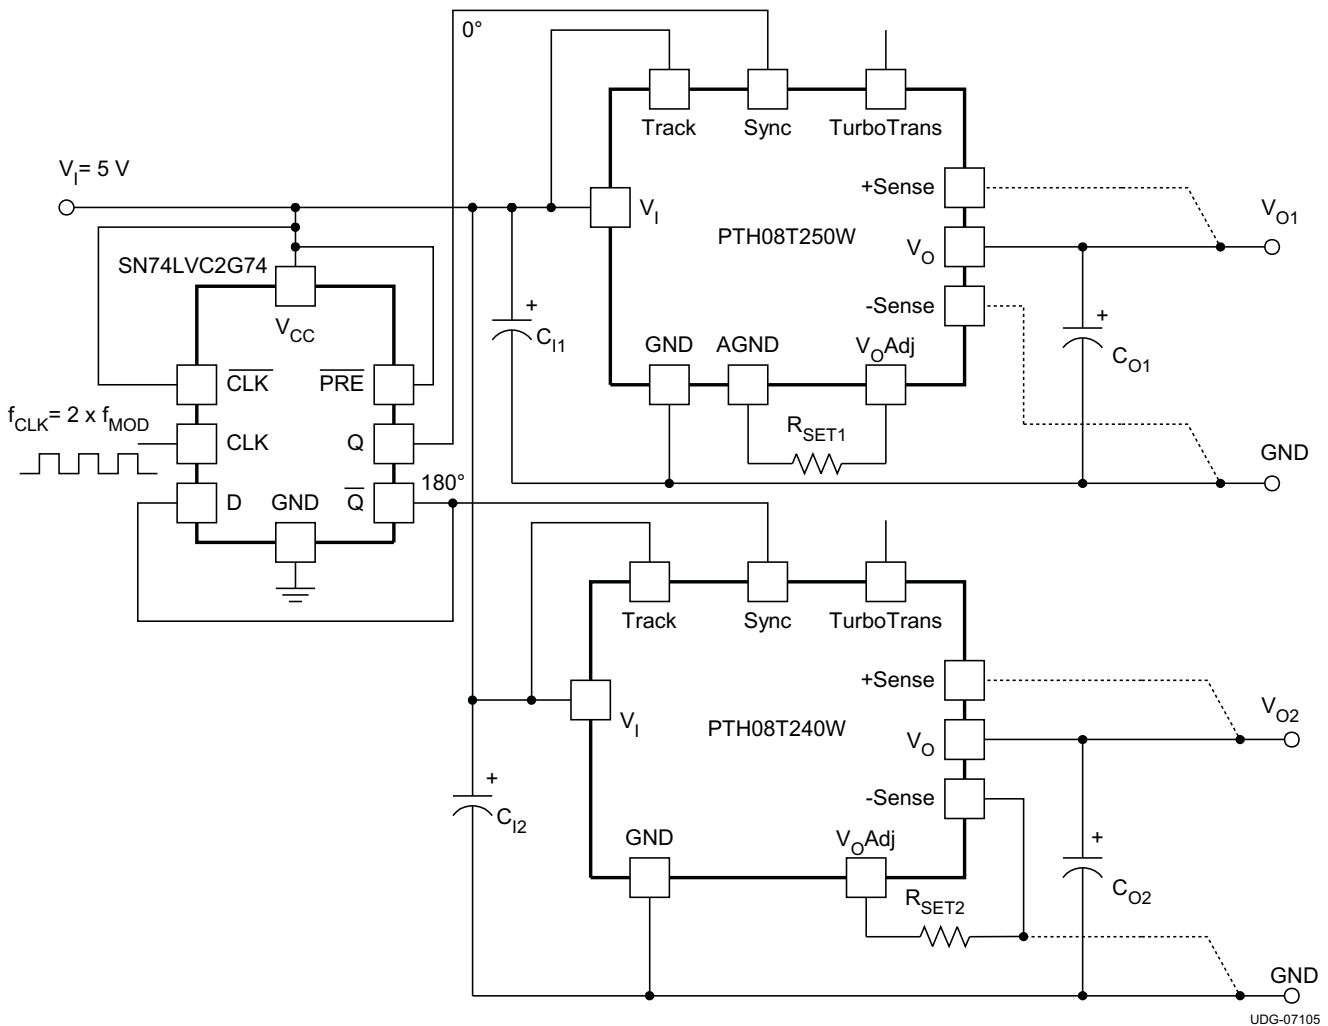

Figure 21. Typical Smart Sync Schematic

Operating the PTH08T250W with a low duty cycle may increase the output voltage ripple. When operating at the nominal switching frequency, input voltages greater than ($V_O \times 12$) may cause the output voltage ripple to increase (up to 2x).

When using Smart Sync, the minimum duty cycle varies as a function of output voltage and switching frequency. Synchronizing to a higher frequency causes greater restrictions on the duty cycle range. For a given switching frequency, Figure 22 shows the operating region where the output voltage ripple meets the electrical specifications. Operation above a given curve may cause the output voltage ripple to increase (up to 2x). For example, a module operating at 400 kHz and an output voltage of 1.2 V, the maximum input voltage that meets the output voltage ripple specification is 11 V. Exceeding 11 V may cause in an increase in output voltage ripple. As shown in Figure 22, operating below 6 V allows operation down to the minimum output voltage over the entire synchronization frequency range without affecting the output voltage ripple. See the Electrical Characteristics table for the synchronization frequency range limits.

The maximum output current that a single module can deliver may also be affected by the sychronization frequency. See Figure 23 below for load current derating when sychronizing at frequencies greater than 330 kHz. First consult the temperature derating graphs in the Typical Characteristics section to determine the maximum output current based on operating conditions. Any derating due to the SmartSync frequency is in addition to the temperature derating.

Figure 22.

Figure 23.

Auto-Track™ Function

The Auto-Track function is unique to the PTH/PTV family, and is available with all POLA products. Auto-Track was designed to simplify the amount of circuitry required to make the output voltage from each module power up and power down in sequence. The sequencing of two or more supply voltages during power up is a common requirement for complex mixed-signal applications that use dual-voltage VLSI ICs such as the TMS320™ DSP family, microprocessors, and ASICs.

How Auto-Track™ Works

Auto-Track works by forcing the module output voltage to follow a voltage presented at the *Track* control pin ⁽¹⁾. This control range is limited to between 0 V and the module set-point voltage. Once the track-pin voltage is raised above the set-point voltage, the module output remains at its set-point ⁽²⁾. As an example, if the *Track* pin of a 2.5-V regulator is at 1 V, the regulated output is 1 V. If the voltage at the *Track* pin rises to 3 V, the regulated output does not go higher than 2.5 V.

When under Auto-Track control, the regulated output from the module follows the voltage at its *Track* pin on a volt-for-volt basis. By connecting the *Track* pin of a number of these modules together, the output voltages follow a common signal during power up and power down. The control signal can be an externally generated master ramp waveform, or the output voltage from another power supply circuit ⁽³⁾. For convenience, the *Track* input incorporates an internal RC-charge circuit. This operates off the module input voltage to produce a suitable rising waveform at power up.

Typical Auto-Track Application

The basic implementation of Auto-Track allows for simultaneous voltage sequencing of a number of Auto-Track compliant modules. Connecting the *Track* inputs of two or more modules forces their track input to follow the same collective RC-ramp waveform, and allows their power-up sequence to be coordinated from a common Track control signal. This can be an open-collector (or open-drain) device, such as a power-up reset voltage supervisor IC. See U3 in [Figure 24](#).

To coordinate a power-up sequence, the Track control must first be pulled to ground potential. This should be done at or before input power is applied to the modules. The ground signal should be maintained for at least 20 ms after input power has been applied. This brief period gives the modules time to complete their internal soft-start initialization ⁽⁴⁾, enabling them to produce an output voltage. A low-cost supply voltage supervisor IC, with a built-in time delay, is an ideal component for automatically controlling the Track inputs at power up.

[Figure 24](#) shows how the TL7712A supply voltage supervisor IC (U3) can be used to coordinate the sequenced power up of PTH08T250W modules. The output of the TL7712A supervisor becomes active above an input voltage of 3.6 V, enabling it to assert a ground signal to the common track control well before the input voltage has reached the module's undervoltage lockout threshold. The ground signal is maintained until approximately 28 ms after the input voltage has risen above U3's voltage threshold, which is 4.3 V. The 28-ms time period is controlled by the capacitor C_T . The value of 2.2 μ F provides sufficient time delay for the modules to complete their internal soft-start initialization. The output voltage of each module remains at zero until the track control voltage is allowed to rise. When U3 removes the ground signal, the track control voltage automatically rises. This causes the output voltage of each module to rise simultaneously with the other modules, until each reaches its respective set-point voltage.

[Figure 25](#) shows the output voltage waveforms after input voltage is applied to the circuit. The waveforms, V_{O1} and V_{O2} , represent the output voltages from the two power modules, U1 (3.3 V) and U2 (1.8 V), respectively. V_{TRK} , V_{O1} , and V_{O2} are shown rising together to produce the desired simultaneous power-up characteristic.

The same circuit also provides a power-down sequence. When the input voltage falls below U3's voltage threshold, the ground signal is re-applied to the common track control. This pulls the track inputs to zero volts, forcing the output of each module to follow, as shown in [Figure 26](#). Power down is normally complete before the input voltage has fallen below the modules' undervoltage lockout. This is an important constraint. Once the modules recognize that an input voltage is no longer present, their outputs can no longer follow the voltage applied at their track input. During a power-down sequence, the fall in the output voltage from the modules is limited by the Auto-Track slew rate capability.

Figure 25. Simultaneous Power Up With Auto-Track Control

Figure 26. Simultaneous Power Down With Auto-Track Control

ADJUSTING THE UNDERVOLTAGE LOCKOUT (UVLO)

The PTH08T250W power modules incorporate an input undervoltage lockout (UVLO). The UVLO feature prevents the operation of the module until there is sufficient input voltage to produce a valid output voltage. This enables the module to provide a clean, monotonic powerup for the load circuit, and also limits the magnitude of current drawn from the regulator’s input source during the power-up sequence.

The UVLO characteristic is defined by the ON threshold (V_{THD}) voltage. Below the ON threshold, the Inhibit control is overridden, and the module does not produce an output. The hysteresis voltage, which is the difference between the ON and OFF threshold voltages, is set at 500 mV. The hysteresis prevents start-up oscillations, which can occur if the input voltage droops slightly when the module begins drawing current from the input source.

The UVLO feature of the PTH08T250W module allows for limited adjustment of the ON threshold voltage. The adjustment is made via the *Inhibit/UVLO Prog* control pin (pin 11) using a single resistor (see Figure 27). When pin 11 is left open circuit, the ON threshold voltage is internally set to its default value, which is 4.3 volts. The ON threshold might need to be raised if the module is powered from a tightly regulated 12-V bus. Adjusting the threshold prevents the module from operating if the input bus fails to completely rise to its specified regulation voltage.

Equation 4 determines the value of R_{UVLO} required to adjust V_{THD} to a new value. The default value is 4.3 V, and it may only be adjusted to a higher value.

$$R_{UVLO} = \frac{230}{V_I - 4.6} \text{ (k}\Omega\text{)} \tag{4}$$

Table 6 lists the standard resistor values for R_{UVLO} for different values of the on-threshold (V_{THD}) voltage.

Table 6. Standard R_{UVLO} values for Various V_{THD} values

V_{THD} (V)	5.5	6.0	6.5	7.0	7.5	8.0	8.5	9.0	9.5	10.0	10.5	11.0
R_{UVLO} (k Ω)	255	165	121	95.3	78.7	68.1	59.0	52.3	46.4	42.2	39.2	35.7

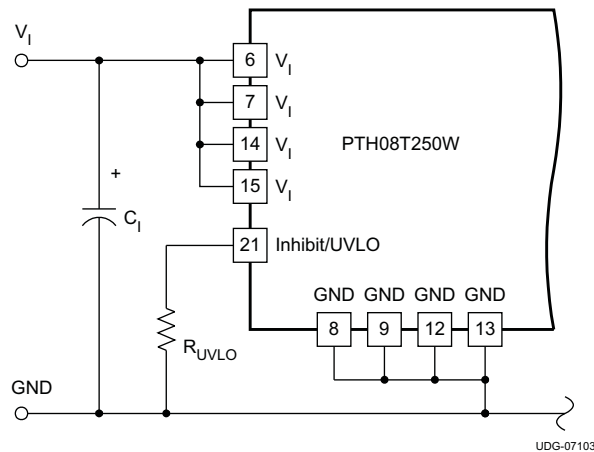

Figure 27. Undervoltage Lockout Adjustment Resistor Placement

CURRENT SHARING

The PTH08T250W module is capable of being configured in parallel with another PTH08T250W module to share load current. To parallel the two modules, it is necessary to configure one module as the Master and one module as the Slave. To configure a module as the Master, connect the CONFIG pin (pin 1) to GND. The CONFIG pin of the Slave must be connected to V_I . In order to share current, pins 2 thru 5 of both the Master and Slave must be connected between the two modules. See Figure 33 for the recommended layout of pins 2 thru 5. The module that is configured as the MASTER is used to control all of the functions of the two modules including Inhibit ON/OFF control, AutoTrack sequencing, TurboTrans, SmartSync, +/- Remote Sense, and Output Voltage Adjust. See the current sharing diagram in Figure 28 for connections. The MASTER and the SLAVE must be powered from the same input voltage supply.

See Figure 28 and Table 7 for a diagram and connection description of each pin when two PTH08T250W modules are being used in a MASTER/SLAVE configuration.

Refer to the application article SLYT320 for more information regarding current sharing PTH08T250W modules.

CURRENT SHARING DIAGRAM

(2) See Layer A in [Figure 33](#) for recommended layout

(3) See Layer B in [Figure 33](#) for recommended layout

Current Sharing and TurboTrans™

When using TurboTrans while paralleling two modules, the TurboTrans resistor, R_{TT}, must be connected from the TurboTrans pin (pin 19) of the Master module to the +Sense pin (pin 17) of the Master module. When paralleling modules the procedure to calculate the proper value of output capacitance and R_{TT} is similar to that explained in the TurboTrans Selection section, however the values must be calculated for a single module. Therefore, the total output current load step must be halved before determining the required output capacitance and the R_{TT} value as explained in the TurboTrans Selection section. The value of output capacitance calculated is the minimum required output capacitance per module and the value of R_{TT} must be calculated using this value of output capacitance. The TurboTrans pin of the Slave module must be left open.

As an example, let's look at a 12-V application requiring a 60 mV deviation during an 30 A load transient. A majority of 470 μF, 10 mΩ output capacitors are used. Use the 12 V, Type B capacitor chart, [Figure 12](#). First, halving the load transient gives 15 A. Dividing 60 mV by 15 A gives 4 mV/A transient voltage deviation per amp of transient load step. Select 4 mV/A on the Y-axis and read across to the 'With TurboTrans' plot. Following this point down to the X-axis gives us a minimum required output capacitance of approximately 1500 μF. This is the minimum required output capacitance per module. Hence, the total minimum output capacitance would be 2x1500 μF = 3000 μF. The required R_{TT} resistor value for 1500 μF can then be calculated or selected from [Table 4](#). The required R_{TT} resistor is approximately 17.4 kΩ.

Current Sharing Thermal Derating Curves

The temperature derating curves in [Figure 29](#) through [Figure 32](#) represent the conditions at which internal components are at or below the manufacturer's maximum operating temperatures. Derating limits apply to two PTH08T250W modules soldered directly to a 100 mm x 200 mm double-sided PCB with 2 oz. copper and the direction of airflow from pins 10 to pins 22. For surface mount packages (AS and AZ suffix), multiple vias must be utilized. Please refer to the mechanical specification for more information.

Current Sharing Layout

In current sharing applications the V_I pins of both modules must be connected to the same input bus. The V_O pins of both modules are connected together to power the load. The GND pins of both modules are connected via the GND plane. Four other inter-connection pins are connected between the modules. Figure 33 shows the required layout of the inter-connection pins for two modules configured to share current. Notice that the Share (pin 2) connection is routed between the Comp (pin 3) and CLKIO (pin 5) connections. AGND (pin 4) should be connected as a thicker trace on an adjacent layer, running parallel to pins 2, 3 and 5. AGND must not be connected to the GND plane.

Figure 33. Recommended Layout of Inter-Connection Pins Between Two Current Sharing Modules

Prebias Startup Capability

A prebias startup condition occurs as a result of an external voltage being present at the output of a power module prior to its output becoming active. This often occurs in complex digital systems when current from another power source is backfed through a dual-supply logic component, such as an FPGA or ASIC. Another path might be via clamp diodes as part of a dual-supply power-up sequencing arrangement. A prebias can cause problems with power modules that incorporate synchronous rectifiers. This is because under most operating conditions, these types of modules can sink as well as source output current.

The PTH family of power modules incorporate synchronous rectifiers, but does not sink current during startup⁽¹⁾, or whenever the Inhibit pin is held low. However, to ensure satisfactory operation of this function, certain conditions must be maintained⁽²⁾. Figure 35 shows an application demonstrating the prebias startup capability. The startup waveforms are shown in Figure 34. Note that the output current (I_O) is negligible until the output voltage rises above the voltage backfed through the intrinsic diodes.

The prebias start-up feature is not compatible with Auto-Track. When the module is under Auto-Track control, it sinks current if the output voltage is below that of a back-feeding source. To ensure a pre-bias hold-off one of two approaches must be followed when input power is applied to the module. The Auto-Track function must either be disabled⁽³⁾, or the module's output held off (for at least 50 ms) using the Inhibit pin. Either approach ensures that the Track pin voltage is above the set-point voltage at start up.

1. Startup includes the short delay (approximately 10 ms) prior to the output voltage rising, followed by the rise of the output voltage under the module's internal soft-start control. Startup is complete when the output voltage has risen to either the set-point voltage or the voltage at the Track pin, whichever is lowest.
2. To ensure that the regulator does not sink current when power is first applied (even with a ground signal applied to the Inhibit control pin), the input voltage must always be greater than the output voltage *throughout* the power-up and power-down sequence.
3. The Auto-Track function can be disabled at power up by immediately applying a voltage to the module's Track pin that is greater than its set-point voltage. This can be easily accomplished by connecting the Track pin to V_I .

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
