

# 2.5-V to 18-V High-Efficiency Adjustable Power-Limiting Hot-Swap Controller With Current Monitor and Overvoltage Protection

 Check for Samples: [TPS24720](#)

## FEATURES

- 2.5-V to 18-V Operation
- Accurate Current Limiting for Startup
- Programmable FET SOA Protection
- Adjustable Current Sense Threshold
- Programmable Fault Timer
- Power-Good Output
- Fast Breaker for Short-Circuit Protection
- Analog Load-Current Monitor Output
- Programmable UV and OV
- Low-current Standby Mode
- FET Fault Detection Flag
- 3-mm × 3-mm, 16-Pin QFN package

## APPLICATIONS

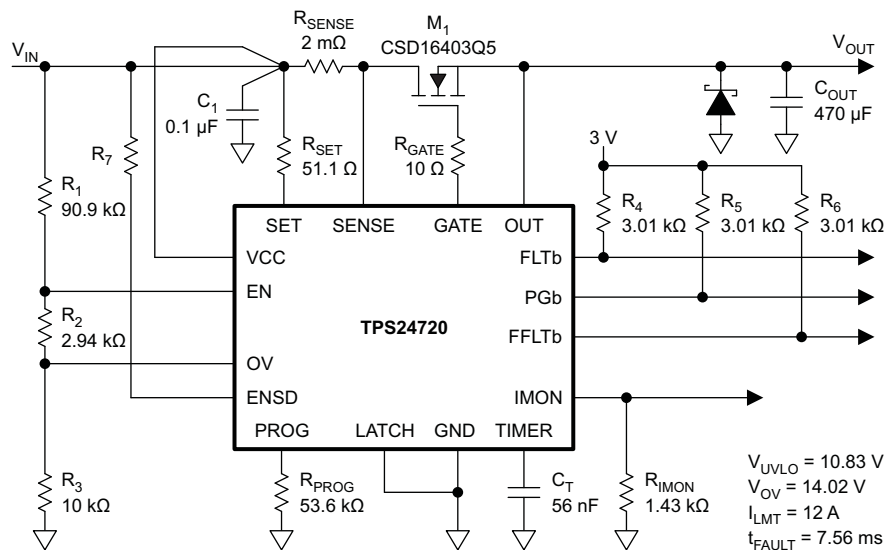

- Server Backplanes
- Storage Area Networks (SAN)
- Telecommunications Mezzanine Cards
- Medical Systems
- Plug-In Modules
- Base Stations

## DESCRIPTION

The TPS24720 is an easy-to-use, full-featured protection device for 2.5-V to 18-V power rails. This hot-swap controller drives an external N-channel MOSFET, while protecting source, load and external MOSFET against multiple potentially damaging events. During startup, load current and MOSFET power dissipation are limited to user-selected values. After startup, currents above the user-selected limit will be allowed to flow until programmed timeout – except in extreme overload events when load is immediately disconnected from source.

Programmable power limiting ensures the external MOSFET operates inside its safe operating area (SOA) at all times. This allows use of smaller FETs while improving system reliability. Power good, Fault, FET Fault, and current monitor outputs are provided for system status monitoring and downstream load control.

### TYPICAL APPLICATION (12 V at 10 A)

### PINOUT

#### RGT Package (Top View)

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

### DEVICE INFORMATION

T <sub>A</sub>	PACKAGE	PART NUMBER <sup>(1)</sup>	FUNCTION	MARKING
–40°C to 85°C	QFN-16	TPS24720	Latched or retry	24720

(1) For the most current package and ordering information, see the Package Option Addendum at the end of this document, or see the TI Web site at [www.ti.com](http://www.ti.com).

### ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range, all voltages referred to GND (unless otherwise noted)

		VALUE	UNIT	
Input voltage range	EN, FFLTb <sup>(1)</sup> , FLTb <sup>(1)</sup> , GATE, OUT, PGb <sup>(1)</sup> , SENSE, SET <sup>(1)</sup> , VCC	–0.3 to 30	V	
	ENSD, OV	–0.3 to 20		
	PROG <sup>(1)</sup>	–0.3 to 0.3		
	[SET, SENSE] to VCC	–0.3 to 0.3		
	IMON, LATCH, TIMER	–0.3 to 5		
Sink current	FFLTb, FLTb, PGb	5	mA	
Source current	PROG	Internally limited		
	IMON	5	mA	
ESD rating	Human-body model	All pins except PGb	2	kV
		PGb	0.5	
	Charged-device model	0.5		
Temperature	Maximum junction, T <sub>J</sub>	Internally limited	°C	

(1) Do not apply voltage directly to these pins.

### THERMAL INFORMATION

THERMAL METRIC <sup>(1)</sup>		TPS24720	UNIT
		QFN (16) PINS	
θ <sub>JA</sub>	Junction-to-ambient thermal resistance	47.3	°C/W
θ <sub>JCtop</sub>	Junction-to-case (top) thermal resistance	63.8	°C/W
θ <sub>JB</sub>	Junction-to-board thermal resistance	20.9	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	1.6	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	21	°C/W
θ <sub>JCbot</sub>	Junction-to-case (bottom) thermal resistance	5.1	°C/W

## RECOMMENDED OPERATING CONDITIONS

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
Input voltage range	ENSD, OV	0		16	V
	SENSE, SET <sup>(1)</sup> , VCC	2.5		18	
	EN, FFLTb, FLTb, PGB, OUT	0		18	
Sink current	FFLTb, FLTb, PGB	0		2	mA
Source current	IMON	0		1	mA
Resistance	PROG	4.99		500	kΩ
External capacitance	TIMER	1			nF
	GATE <sup>(2)</sup>			1	μF
Operating junction temperature range, T <sub>J</sub>		-40		125	°C

(1) Do not apply voltage directly to these pins.

(2) External capacitance tied to GATE should be in series with a resistor no less than 1 kΩ.

## ELECTRICAL CHARACTERISTICS

 $-40^{\circ}\text{C} \leq T_J \leq 125^{\circ}\text{C}$ ,  $V_{CC} = 12\text{ V}$ ,  $V_{EN} = 3\text{ V}$ ,  $V_{ENSD} = 3\text{ V}$ ,  $R_{SET} = 190\ \Omega$ ,  $R_{IMON} = 5\text{ k}\Omega$ , and  $R_{PROG} = 50\text{ k}\Omega$  to GND.

All voltages referenced to GND, unless otherwise noted.

PARAMETER	CONDITIONS	MIN	NOM	MAX	UNIT
<b>VCC</b>					
UVLO threshold, rising		2.2	2.32	2.45	V

**PIN FUNCTIONS**

NAME	PIN	I/O	DESCRIPTION
EN	1	I	Active-high enable input. Logic input. Connects to resistor divider.
ENSD	16	I	Pull low to put device into low-current standby mode. Logic input.
FFLTb	9	O	Active-low, open-drain FET fault indicator. Indicates shorted MOSFET when output is off.
FLTb	13	O	Active-low, open-drain output indicates overload fault timer has turned MOSFET off.
GATE	10	O	Gate driver output for external MOSFET
GND	4	–	Ground
IMON	6	O	Analog load current limit program point. Connect R <sub>IMON</sub> to ground.

**PIN FUNCTIONS (continued)**

NAME	PIN	I/O	DESCRIPTION
LATCH	14	I	Latch or retry mode select input. Latch when floating or connected to a logic-level voltage; retry when connected to GND.
OUT	8	I	Output voltage sensor for monitoring MOSFET power.
OV	5	I	Overshoot comparator input. Connects to resistor divider. GATE is pulled low when OV exceeds the threshold.
PGb	15	O	Active-low, open-drain power-good indicator. Status is determined by the voltage across the MOSFET.
PROG	2	I	Power-limiting programming pin. A resistor from this pin to GND sets the maximum power dissipation for the FET.
SENSE	11	I	Current-sensing input for resistor shunt from VCC to SENSE.
SET	7	I	Current-limit programming set pin. A resistor is connected from this pin to VCC.
TIMER	3	I/O	A capacitor connected from this pin to GND provides a fault timing function.
VCC	12	I	Input-voltage sense and power supply
Thermal pad	—	—	Tied to GND

**DETAILED PIN DESCRIPTIONS**

The following description relies on the typical application diagram shown on the front page of this data sheet, as well as the functional block diagram in [Figure 5](#).

**EN:** Applying a voltage of 1.35 V or more to this pin enables the gate driver. The addition of an external resistor divider allows the EN pin to serve as an undervoltage monitor. Cycling EN low and then back high resets the TPS24720 that has latched off due to a fault condition. This pin should not be left floating.

**ENSD:** When this pin is pulled low, it shuts off all internal circuitry and thus places the device in a low-current standby mode. While in standby, the PGb, FLTb, and FFLTb outputs assume high-impedance states. A 20-k $\Omega$  resistor pulls GATE to GND in standby. This is a much weaker pulldown than the 11 mA drawn while the part is disabled (e.g., by EN, UVLO, OV, or overload fault current). Applications requiring rapid turnoff should disable the device using the EN pin before pulling ENSD low. This pin is preferably pulled up to a positive voltage from 2 V to 18 V, if not otherwise connected.

**FFLTb:** This active-low open-drain output pulls low if  $V_{VCC}$  is higher than the UVLO rising threshold and the voltage on the IMON pin exceeds 103 mV when EN is disabled. The presence of this voltage indicates that current continues to flow through the external circuitry even though the external MOSFET has been turned off. This presumably indicates a shorted MOSFET. FFLTb assumes a high impedance if one of the following conditions occurs:

- ENSD is pulled low.
- Temperature on the die exceeds the OTSD shutdown threshold.
- $V_{VCC}$  drops below the UVLO falling threshold.

FFLTb also asserts if  $V_{VCC}$  is higher than the UVLO rising threshold, GATE is disabled by OV, and the voltage on the IMON pin exceeds 103 mV. This pin can be left floating when not used.

**FLTb:** This active-low open-drain output pulls low when the TPS24720 has remained in current limit long enough for the fault timer to expire. The behavior of the FLTb pin depends on the status of the LATCH pin. If the LATCH pin is held high or left floating, the TPS24720 operates in latch mode. If the LATCH pin is held low, the TPS24720 operates in retry mode. In latch mode, a fault timeout disables the external MOSFET and holds FLTb low. The latched mode of operation is reset by cycling EN, VCC, or ENSD. In retry mode, a fault timeout first disables the external MOSFET, next waits sixteen cycles of TIMER charging and discharging, and finally attempts a restart. This process repeats as long as the fault persists. In retry mode, the FLTb pin is pulled low whenever the external MOSFET is disabled by the fault timer. In a sustained fault, the FLTb waveform becomes a train of pulses. The FLTb pin does not assert if the external MOSFET is disabled by EN, ENSD, OV, overtemperature shutdown, or UVLO. This pin can be left floating when not used.

**GATE:** This pin provides gate drive to the external MOSFET. A charge pump sources 30  $\mu\text{A}$  to enhance the external MOSFET. A 13.9-V clamp between GATE and VCC limits the gate-to-source voltage, because  $V_{\text{VCC}}$  is very close to  $V_{\text{OUT}}$  in normal operation. During start-up, a transconductance amplifier regulates the gate voltage of  $M_1$  to provide inrush current limiting. The TIMER pin charges timer capacitor  $C_T$  during the inrush. Inrush current limiting continues until the  $V_{(\text{GATE} - \text{VCC})}$  exceeds the Timer Activation Voltage (6 V for  $V_{\text{VCC}} = 12$  V). Then the TPS24720 enters into circuit-breaker mode. The Timer Activation Voltage is defined as a threshold voltage. When  $V_{(\text{GATE}-\text{VCC})}$  exceeds this threshold voltage, the inrush operation is finished and the TIMER stops sourcing current and begins sinking current. In the circuit-breaker mode, the current flowing in  $R_{\text{SENSE}}$  is compared with the current-limit threshold derived from the MOSFET power-limit scheme (see PROG). If the current flowing in  $R_{\text{SENSE}}$  exceeds the current limit threshold, then MOSFET  $M_1$  is turned off. The GATE pin is disabled by the following three mechanisms:

1. GATE is pulled down by an 11-mA current source when
  - The fault timer expires during an overload current fault ( $V_{\text{IMON}} > 675$  mV)
  - $V_{\text{EN}}$  is below its falling threshold
  - $V_{\text{VCC}}$  drops below the UVLO threshold
  - $V_{\text{OV}}$  is above its rising threshold
2. GATE is pulled down by a 1-A current source for 13.5  $\mu\text{s}$  when a hard output short circuit occurs and  $V_{(\text{VCC} - \text{SENSE})}$  is greater than 60 mV, i.e., the fast-trip shutdown threshold. After fast-trip shutdown is complete, an 11-mA sustaining current ensures that the external MOSFET remains off.
3. GATE is discharged by a 20-k $\Omega$  resistor to GND if the chip die temperature exceeds the OTSD rising threshold or ENSD is pulled low.

GATE remains low in latch mode and attempts a restart periodically in retry mode.

If used, any capacitor connecting GATE and GND should not exceed 1  $\mu\text{F}$  and it should be connected in series with a resistor of no less than 1 k $\Omega$ . No external resistor should be directly connected from GATE to GND or from GATE to OUT.

**GND:** This pin is connected to system ground.

**IMON:** A resistor connected from this pin to GND scales the current-limit and power-limit settings, as illustrated in [Figure 5](#). The voltage present at this pin is proportional to the current flowing through sense resistor  $R_{\text{SENSE}}$ . This voltage can be used as a means of monitoring current flow through the system. The value of  $R_{\text{IMON}}$  can be calculated from [Equation 3](#). This pin should not have a bypass capacitor or any other load except for  $R_{\text{IMON}}$ .

**LATCH:** This pin determines whether the TPS24720 operates in latch mode or retry mode. Applying a voltage of 2 V to 5 V to this pin or allowing it to float selects latch mode. Tying the pin to ground selects retry mode. In latch mode, an overload current fault disables the TPS24720 until EN, ENSD, or VCC is cycled. In retry mode, the TPS24720 automatically attempts a restart after every sixteen cycles of TIMER charging and discharging. In a sustained fault in retry mode, the external MOSFET conducts 3.93% of the time; i.e., the duty ratio is 0.0393. If the LATCH pin is allowed to float, then its open-circuit voltage is approximately 2.28 V.

**OUT:** This pin allows the controller to measure the drain-to-source voltage across the external MOSFET  $M_1$ . The power-good indicator (PGb) relies on this information, as does the power-limiting engine. The OUT pin should be protected from negative voltage transients by a clamping diode or sufficient capacitors. A Schottky diode of 3 A / 40 V in a SMC package is recommended as a clamping diode for high-power applications. The OUT pin should be bypassed to GND with a low-impedance ceramic capacitor in the range of 10 nF to 1  $\mu\text{F}$ .

**OV:** This pin is used to program the device overvoltage level. A voltage of more than 1.35 V on this pin turns off the external MOSFET. A resistor divider connected from VCC to this pin provides overvoltage protection for the downstream load. This pin should be tied to GND when not used.

**PGb:** This active-low, open-drain output is intended to interface to downstream dc/dc converters or monitoring circuits. PGb pulls low after the drain-to-source voltage of the FET has fallen below 170 mV and a 3.4-ms deglitch delay has elapsed. It goes open-drain when  $V_{\text{DS}}$  exceeds 240 mV. PGb assumes high-impedance status after a 3.4-ms deglitch delay once  $V_{\text{DS}}$  of  $M_1$  rises up, resulting from GATE being pulled to GND at any of the following conditions :

- An overload current fault occurs ( $V_{\text{IMON}} > 675$  mV).
- A hard output short circuit occurs, leading to  $V_{(\text{VCC} - \text{SENSE})}$  greater than 60 mV, i.e., the fast-trip shutdown threshold has been exceeded.
- $V_{\text{EN}}$  is below its falling threshold.

- $V_{\text{ENSD}}$  is below its threshold.
- $V_{\text{VCC}}$  drops below the UVLO threshold.
- $V_{\text{OV}}$  is above its rising threshold.
- Die temperature exceeds the OTSD threshold.

This pin can be left floating when not used.

**PROG:** A resistor from this pin to GND sets the maximum power permitted in the external MOSFET  $M_1$  during inrush. Do not apply a voltage to this pin. If the constant power limit is not desired, use a PROG resistor of 4.99 k $\Omega$ . To set the maximum power, use [Equation 1](#),

$$P_{\text{LIM}} = \frac{3125}{R_{\text{PROG}} \times R_{\text{SENSE}}} \quad (1)$$

where  $P_{\text{LIM}}$  is the allowed power limit of MOSFET  $M_1$ .  $R_{\text{SENSE}}$  is the load-current-monitoring resistor connected between the VCC pin and the SENSE pin.  $R_{\text{PROG}}$  is the resistor connected from the PROG pin to GND. Both  $R_{\text{PROG}}$  and  $R_{\text{SENSE}}$  are in ohms and  $P_{\text{LIM}}$  is in watts.  $P_{\text{LIM}}$  is determined by the maximum allowed thermal stress of MOSFET  $M_1$ , given by [Equation 2](#),

$$P_{\text{LIM}} < \frac{T_{\text{J(MAX)}} - T_{\text{C(MAX)}}}{R_{\theta\text{JC(MAX)}}} \quad (2)$$

where  $T_{\text{J(MAX)}}$  is the maximum desired transient junction temperature and  $T_{\text{C(MAX)}}$  is the maximum case temperature prior to a start or restart.  $R_{\theta\text{JC(MAX)}}$  is the junction-to-case thermal impedance of the pass MOSFET  $M_1$  in units of  $^{\circ}\text{C}/\text{W}$ . Both  $T_{\text{J(MAX)}}$  and  $T_{\text{C(MAX)}}$  are in  $^{\circ}\text{C}$ .

**SENSE:** This pin connects to the negative terminal of  $R_{\text{SENSE}}$ . It provides a means of sensing the voltage across this resistor, as well as a way to monitor the drain-to-source voltage across the external FET. The current limit  $I_{\text{LIM}}$  is set by [Equation 3](#).

$$I_{\text{LIM}} = \frac{0.675 \text{ V} \times R_{\text{SET}}}{R_{\text{IMON}} \times R_{\text{SENSE}}} \quad (3)$$

A fast-trip shutdown occurs when  $V_{(\text{VCC} - \text{VSENSE})}$  exceeds 60 mV.

**SET:** A resistor  $R_{\text{SET}}$  is connected from this pin to the positive terminal of  $R_{\text{SENSE}}$ . This resistor scales the current limit and power limit settings. It coordinates with  $R_{\text{IMON}}$  and  $R_{\text{SENSE}}$  to determine the current limit value. The value of  $R_{\text{SET}}$  can be calculated from [Equation 3](#) (see SENSE).

**TIMER:** A capacitor  $C_{\text{T}}$  connected from the TIMER pin to GND determines the overload fault timing. TIMER sources 10  $\mu\text{A}$  when an overload is present, and discharges  $C_{\text{T}}$  at 10  $\mu\text{A}$  otherwise.  $M_1$  is turned off when  $V_{\text{TIMER}}$  reaches 1.35 V. In an application implementing auto-retry after a fault, this capacitor also determines the period before the external MOSFET is re-enabled. A minimum timing capacitance of 1 nF is recommended to ensure proper operation of the fault timer. The value of  $C_{\text{T}}$  can be calculated from the desired fault time  $t_{\text{FLT}}$ , using [Equation 4](#).

$$C_{\text{T}} = \frac{10 \mu\text{A}}{1.35 \text{ V}} \times t_{\text{FLT}} \quad (4)$$

As is explained in the description of the LATCH pin, either latch mode or retry mode occurs if the load current exceeds the current limit threshold or the fast-trip shutdown threshold, depending on the status of the LATCH pin. While in latch mode, the TIMER pin continues to charge and discharge the attached capacitor periodically. In retry mode, the external MOSFET is disabled for sixteen cycles of TIMER charging and discharging. The TIMER pin is pulled to GND by a 2-mA current source at the end of the 16<sup>th</sup> cycle of charging and discharging. The external MOSFET is then re-enabled. The TIMER pin capacitor,  $C_{\text{T}}$ , can also be discharged to GND during latch mode or retry mode in the following two ways:

1. A 2-mA current sinks TIMER whenever any of the following occurs:
  - $V_{\text{EN}}$  is below its falling threshold.
  - $V_{\text{VCC}}$  drops below the UVLO threshold.
  - $V_{\text{OV}}$  is above its rising threshold.
2. A 100-k $\Omega$  resistor is connected to TIMER and discharges  $C_{\text{T}}$  at the moment when  $V_{\text{ENSD}}$  drops below its threshold.

TIMER is not affected when the die temperature exceeds the OTSD threshold.

**VCC:** This pin performs three functions. First, it provides biasing power to the integrated circuit. Second, it serves as an input to the power-on reset (POR) and undervoltage lockout (UVLO) functions. The VCC trace from the integrated circuit should connect directly to the positive terminal of  $R_{SENSE}$  to minimize the voltage sensing error. Bypass capacitor  $C_1$ , shown in the typical application diagram on the front page, should be connected to the positive terminal of  $R_{SENSE}$ . A capacitance of at least 10 nF is recommended.

TYPICAL CHARACTERISTICS

## SYSTEM OPERATION

### INTRODUCTION

The TPS24720 provides all the features needed for a positive hot-swap controller. These features include:

- Undervoltage lockout
- Adjustable (system-level) enable
- Turn-on inrush limiting
- High-side gate drive for an external N-channel MOSFET
- MOSFET protection by power limiting
- Adjustable overload timeout, also called an electronic circuit breaker
- Charge-complete indicator for downstream converter coordination
- A choice of latch or automatic restart mode
- A low-power disable mode accessed by holding ENSD low
- MOSFET short detection
- Load overvoltage protection

The typical application diagram, shown on the front page of this datasheet, and oscilloscope plots, shown in [Figure 29](#) through [Figure 31](#) and [Figure 33](#) through [Figure 36](#), demonstrate many of the functions described previously.

### BOARD PLUG-IN

[Figure 29](#) and [Figure 30](#) illustrate the inrush current that flows when a hot swap board under the control of the TPS24720 is plugged into a system bus. Only the bypass capacitor charge current and small bias currents are evident when a board is first plugged in. The TPS24720 is held inactive for a short period while internal voltages stabilize. In this short period, GATE, PROG, and TIMER are held low and PGb, FLTb, and FFLTb are held open-drain. When the voltage on the internal VCC rail exceeds approximately 1.5 V, the power-on reset (POR) circuit initializes the TPS24720 and a start-up cycle is ready to take place.

GATE, PROG, TIMER, PGb, FLTb and FFLTb are released after the internal voltages have stabilized and the external EN (enable) thresholds have been exceeded. The part begins sourcing current from the GATE pin to turn on MOSFET M<sub>1</sub>. The TPS24720 monitors both the drain-to-source voltage across MOSFET M<sub>1</sub> and the drain current passing through it. Based on these measurements, the TPS24720 limits the drain current by controlling the gate voltage so that the power dissipation within the MOSFET does not exceed the power limit programmed by the user. The current increases as the voltage across the MOSFET decreases until finally the current reaches the current limit I<sub>LIM</sub>.

## INRUSH OPERATION

When the TPS24720 activates the MOSFET  $M_1$ , a current flows into the downstream bulk storage capacitors. When this current exceeds the limit set by the power-limit engine, the gate of the MOSFET is regulated by a feedback loop to make the MOSFET current rise in a controlled manner. This not only limits the capacitor-charging inrush current but it also limits the power dissipation of the MOSFET to safe levels. A more complete explanation of the power-limiting scheme is given in the section entitled *Action of the Constant Power Engine*. At the instant when the current in  $R_{SENSE}$  reaches the programmed limit, the TIMER pin begins to charge the timing capacitor  $C_T$  with a current of approximately 10  $\mu\text{A}$ . The TIMER pin continues to charge  $C_T$  until  $V_{(GATE - V_{CC})}$  reaches the timer activation voltage (6 V for  $V_{VCC} = 12\text{ V}$ ). The TIMER then begins to discharge  $C_T$  with a current of approximately 10  $\mu\text{A}$ . This indicates that the inrush mode is finished. If the TIMER exceeds its upper threshold of 1.35 V before  $V_{(GATE - V_{CC})}$  reaches the timer activation voltage, the GATE pin is pulled to GND and the hot-swap circuit enters either latch mode or auto-retry mode, depending upon the status of the LATCH pin (see LATCH in *Detailed Pin Descriptions*).

The power limit feature is disabled once the inrush operation is finished and the hotswap circuit becomes a circuit breaker. The TPS24720 will turn off the MOSFET  $M_1$  after a fault timer period once the load exceeds the current limit threshold.

## ACTION OF THE CONSTANT-POWER ENGINE

Figure 30 illustrates the operation of the constant-power engine during start-up. The circuit used to generate the waveforms of Figure 30 was programmed to a power limit of 29.3 W by means of the resistor connected between PROG and GND. At the moment current begins to flow through the MOSFET, a voltage of 12 V appears across it (input voltage  $V_{VCC} = 12\text{ V}$ ), and the constant-power engine therefore allows a current of 2.44 A (equal to 29.3 W divided by 12 V) to flow. This current increases in inverse ratio as the drain-to-source voltage diminishes, so as to maintain a constant dissipation of 29.3 W. The constant-power engine adjusts the current by altering the reference signal fed to the current limit amplifier. The lower part of Figure 31 shows the measured power

dissipated within the MOSFET, labeled *FET PWR*, remaining substantially constant during this period of operation, which ends when the current through the MOSFET reaches the current limit  $I_{LIM}$ . This behavior can be considered a form of foldback limiting, but unlike the standard linear form of foldback limiting, it allows the power device to operate near its maximum capability, thus reducing the start-up time and minimizing the size of the required MOSFET.

C002

## CIRCUIT BREAKER AND FAST TRIP

The TPS24720 monitors load current by sensing the voltage across  $R_{SENSE}$ . The TPS24720 incorporates two distinct thresholds: a current-limit threshold and a fast-trip threshold.

The functions of circuit breaker and fast-trip turn off are shown in [Figure 31](#) through [Figure 34](#).

[Figure 31](#) shows the behavior of the TPS24720 when a fault in the output load causes the current passing through  $R_{SENSE}$  to increase to a value above the current limit but less than the fast-trip threshold. When the current exceeds the current-limit threshold, a current of approximately  $10 \mu\text{A}$  begins to charge timing capacitor  $C_T$ . If the voltage on  $C_T$  reaches 1.35 V, then the external MOSFET is turned off. The TPS24720 either latches off or commences a restart cycle, depending upon the state of the LATCH pin. In either event, fault pin FLTB pulls low to signal a fault condition. Overload between the current limit and the fast-trip threshold is permitted for this period. This shutdown scheme is sometimes called an electronic circuit breaker.

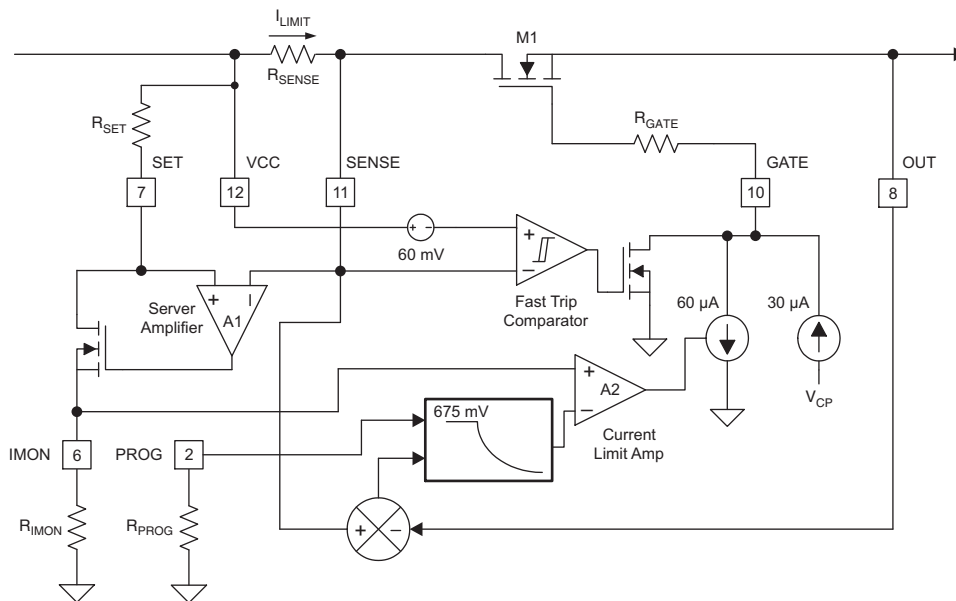

The fast-trip threshold protects the system against a severe overload or a dead short circuit. When the voltage across the sense resistor  $R_{SENSE}$  exceeds the 60-mV fast-trip threshold, the GATE pin immediately pulls the external MOSFET gate to ground with approximately 1 A of current. This extremely rapid shutdown may generate disruptive transients in the system, in which case a low-value resistor inserted between the GATE pin and the MOSFET gate can be used to moderate the turn off current. The fast-trip circuit holds the MOSFET off for only a few microseconds, after which the TPS24720 turns back on slowly, allowing the current-limit feedback loop to take over the gate control of  $M_1$ . Then the hot-swap circuit goes into latch mode or auto-retry mode, depending on pre-determined conditions. [Figure 33](#) and [Figure 34](#) illustrate the behavior of the system when the current exceeds the fast-trip threshold.

## AUTOMATIC RESTART

If LATCH is connected to GND, then the TPS24720 automatically initiates a restart after a fault has caused it to turn off the external MOSFET  $M_1$ . Internal control circuits use  $C_T$  to count 16 cycles before re-enabling  $M_1$  as shown in Figure 35. This sequence repeats if the fault persists. The timer has a 1 : 1 charge-to-discharge current ratio. For the very first cycle, the TIMER pin starts from 0 V and rises to the upper threshold of 1.35 V and subsequently falls to 0.35 V before restarting. For the following 16 cycles, 0.35 V is used as the lower threshold. This small duty cycle often reduces the average short-circuit power dissipation to levels associated with normal operation and eliminates special thermal considerations for surviving a prolonged output short.

## PGb, FLTb, AND TIMER OPERATIONS

The open-drain PGb output provides a deglitched end-of-inrush indication based on the voltage across  $M_1$ . PGb is useful for preventing a downstream dc/dc converter from starting while its input capacitor  $C_{OUT}$  is still charging. PGb goes active-low about 3.4 ms after  $C_{OUT}$  is charged. This delay allows  $M_1$  to fully turn on and any transients in the power circuits to end before the converter starts up. This type of sequencing prevents the downstream converter from demanding full current before the power-limiting engine allows the MOSFET to conduct the full current set by the current limit  $I_{LIM}$ . Failure to observe this precaution may prevent the system from starting. The pullup resistor shown on the PGb pin in the typical application diagram on the front page is illustrative only; the actual connection to the converter depends on the application. The PGb pin may indicate that inrush has ended before the MOSFET is fully enhanced, but the downstream capacitor will have been charged to substantially its full operating voltage. Care should be taken to ensure that the MOSFET on-resistance is sufficiently small to ensure that the voltage drop across this transistor is less than the minimum power-good threshold of 140 mV. After the hot-swap circuit successfully starts up, the PGb pin can return to a high-impedance status whenever the drain-to-source voltage of MOSFET  $M_1$  exceeds its upper threshold of 340 mV, which presents the downstream converters a warning flag. This flag may occur as a result of overload fault, output short fault, input overvoltage, higher die temperature, or the GATE shutdown by UVLO, EN or ENSD.

FLTb is an indicator that the allowed fault-timer period during which the load current can exceed the programmed current limit (but not the fast-trip threshold) expires. The fault timer starts when a current of approximately 10  $\mu$ A begins to flow into the external capacitor,  $C_T$ , and ends when the voltage of  $C_T$  reaches TIMER upper threshold, i.e., 1.35 V. FLTb pulls low at the end of the fault timer. Otherwise, FLTb assumes a high-impedance state.

The fault-timer state requires an external capacitor  $C_T$  connected between the TIMER pin and GND pin. The duration of the fault timer is the charging time of  $C_T$  from 0 V to its upper threshold of 1.35 V. The fault timer begins to count under any of the following three conditions:

1. In the inrush mode, TIMER begins to source current to the timer capacitor,  $C_T$ , when MOSFET  $M_1$  is enabled. TIMER begins to sink current from the timer capacitor,  $C_T$  when  $V_{(GATE - VCC)}$  exceeds the timer activation voltage (see the *Inrush Operation* section). If  $V_{(GATE - VCC)}$  does not reach the timer activation voltage before TIMER reaches 1.35 V, then the TPS24720 disables the external MOSFET  $M_1$ . After the MOSFET turns off, the timer goes into either latch mode or retry mode, depending on the LATCH pin status.
2. In an overload fault, TIMER begins to source current to the timer capacitor,  $C_T$ , when the load current exceeds the programmed current limits. When the timer capacitor voltage reaches its upper threshold of 1.35 V, TIMER begins to sink current from the timer capacitor,  $C_T$ , and the GATE pin is pulled to ground. After the fault timer period, TIMER may go into latch mode or retry mode, depending on the LATCH pin status.
3. In output short-circuit fault, TIMER begins to source current to the timer capacitor,  $C_T$ , when the load current exceeds the programmed current limits following a fast-trip shutdown of  $M_1$ . When the timer capacitor voltage reaches its upper threshold of 1.35 V, TIMER begins to sink current from the timer capacitor,  $C_T$ , and the GATE pin is pulled to ground. After the fault timer period, TIMER may go into latch mode or retry mode, depending on the LATCH pin status.

If the fault current drops below the programmed current limit within the fault timer period,  $V_{TIMER}$  decreases and the pass MOSFET remains enabled.

The behaviors of TIMER are different in the latch mode and retry mode. If the timer capacitor reaches the upper threshold of 1.35 V, then:

- In latch mode, the TIMER pin continues to charge and discharge the attached capacitor periodically until TPS24720 is disabled by UVLO, EN, ENSD, or OV, as shown in [Figure 36](#).
- In retry mode, TIMER charges and discharges  $C_T$  between the lower threshold of 0.35 V and the upper threshold of 1.35 V for sixteen cycles before the TPS24720 attempts to re-start. The TIMER pin is pulled to GND at the end of the 16<sup>th</sup> cycle of charging and discharging and then ramps from 0 V to 1.35 V for the initial half-cycle in which the GATE pin sources current. This periodic pattern is stopped once the overload fault is removed or the TPS24720 is disabled by UVLO, EN, ENSD, or OV.

## OVERTEMPERATURE SHUTDOWN

The TPS24720 includes a built-in overtemperature shutdown circuit designed to disable the gate driver if the die temperature exceeds approximately 140°C. An overtemperature condition also causes the FLTb, FFLTb and PGb pins to go to high-impedance states. Normal operation resumes once the die temperature has fallen approximately 10°C.

## START-UP OF HOT-SWAP CIRCUIT BY VCC OR EN

The connection and disconnection between a load and the input power bus are controlled by turning on and turning off the MOSFET,  $M_1$ .

The TPS24720 has two ways to turn on MOSFET  $M_1$ :

- Increasing  $V_{VCC}$  above UVLO upper threshold while EN is already higher than its upper threshold sources current to the GATE pin. After an inrush period, the TPS24720 fully turns on MOSFET  $M_1$ .
- Increasing EN above its upper threshold while  $V_{VCC}$  is already higher than the UVLO upper threshold sources current to the GATE pin. After an inrush period, the TPS24720 fully turns on MOSFET  $M_1$ .

The EN pin can be used to start up the TPS24720 at a selected input voltage  $V_{VCC}$ .

To isolate the load from the input power bus, the GATE pin sinks current and pulls the gate of MOSFET  $M_1$  low. The MOSFET can be disabled by any of the following conditions: UVLO, EN, ENSD, load current above the current-limit threshold, hard short at load, OV, or OTSD. Three separate mechanisms pull down the GATE pin:

1. GATE is pulled down by an 11-mA current source when any of the following occurs.
  - The fault timer expires during an overload current fault ( $V_{IMON} > 675$  mV).
  - $V_{EN}$  is below its falling threshold.
  - $V_{VCC}$  drops below the UVLO threshold.
  - $V_{OV}$  is above its rising threshold.
2. GATE is pulled down by a 1-A current source for 13.5  $\mu$ s when a hard output short circuit occurs and  $V_{(VCC - SENSE)}$  is greater than 60 mV, i.e., the fast-trip shutdown threshold. After fast-trip shutdown is complete, an 11-mA sustaining current ensures that the external MOSFET remains off.
3. GATE is discharged by a 20-k $\Omega$  resistor to GND if the chip die temperature exceeds the OTSD rising threshold or ENSD is pulled low.

## MINIMIZATION OF POWER DISSIPATION AT STANDBY BY ENSD

The ENSD pin enables the use of TPS24720 in applications requiring a low-power standby mode. When this pin is pulled below its threshold voltage, all the internal circuitry is switched off and the GATE pin is discharged to GND through a 20-k $\Omega$  resistor. Thus, the MOSFET is disabled and power consumption is kept to a minimum. The correct procedure to go into standby mode is first to shut down the TPS24720 by using the EN pin and then to pull the ENSD pin low.

## FAULT DETECTION OF MOSFET SHORT WITH FFLTb

One of the salient features of the TPS24720 is the detection of short-circuited MOSFETs by the FFLTb pin. The FFLTb is pulled low to indicate a FET short if all the following conditions occur.

- EN is below its threshold voltage.
- $V_{VCC}$  is above the UVLO threshold.
- $V_{IMON} > 103$  mV.

The fact that GATE is turned off but current is still flowing through  $R_{SENSE}$  indicates a drain-to-source short.

## DESIGN EXAMPLE: POWER-LIMITED START-UP

This design example assumes a 12-V system voltage with an operating tolerance of  $\pm 2$  V. The rated load current is 10 A, corresponding to a dc load of 1.2  $\Omega$ . If the current exceeds 12 A, then the controller should shut down and then attempt to restart. Ambient temperatures may range from 20°C to 50°C. The load has a minimum input capacitance of 470  $\mu$ F. [Figure 37](#) shows a simplified system block diagram of the proposed application.

This design procedure seeks to control the junction temperature of MOSFET  $M_1$  under both static and transient conditions by proper selection of package, cooling,  $r_{DS(on)}$ , current limit, fault timeout, and power limit. The design procedure further assumes that a unit running at full load and maximum ambient temperature experiences a brief input power interruption sufficient to discharge  $C_{OUT}$ , but short enough to keep  $M_1$  from cooling. A full  $C_{OUT}$  recharge then takes place. Adjust this procedure to fit the application and design criteria.

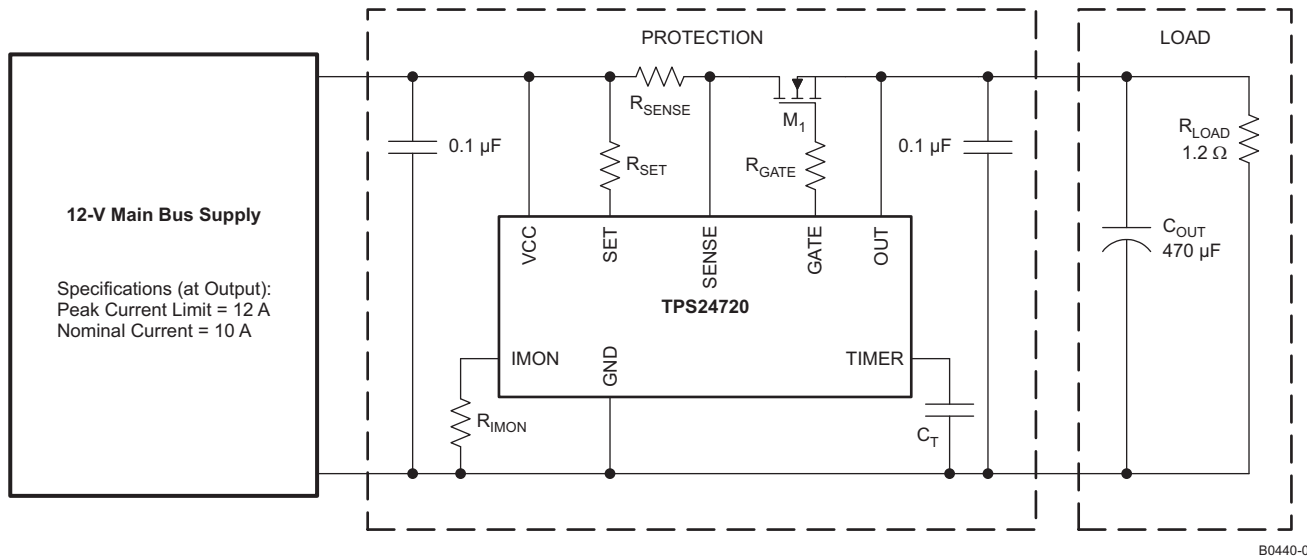

Figure 37. Simplified Block Diagram of the System Constructed in the Design Example

**STEP 1. Choose  $R_{SENSE}$ ,  $R_{SET}$ , and  $R_{IMON}$**

The recommended range of the current-limit threshold voltage,  $V_{(VCC - SENSE)}$ , extends from 10 mV to 42 mV. Values near the low threshold of 10 mV may be affected by system noise. Values near the upper threshold of 42 mV may be too close to the minimum fast-trip threshold voltage of 52 mV. Values near the middle of this range help minimize both concerns.

To achieve high efficiency, the power dissipation in  $R_{SENSE}$  must be kept to a minimum. A  $R_{SENSE}$  of 2 m $\Omega$  develops a voltage of 24 mV at the specified peak current limit of 12 A, while dissipating only 200 mW at the rated 10-A current. This represents a 0.17% power loss.

For best performance, a current of approximately 0.5 mA (referring to the RECOMMENDED OPERATING CONDITIONS table) should flow into the SET pin and out of the IMON pin when the TPS24720 is in current limit. The voltage across  $R_{SET}$  nominally equals the voltage across  $R_{SENSE}$ , or 24 mV. Dividing 24 mV by 0.5 mA gives a recommended value of  $R_{SET}$  of 48  $\Omega$ . A 51.1- $\Omega$ , 1% resistor was chosen. Using Equation 3, the value of  $R_{IMON}$  must equal 1437  $\Omega$ , or as near as practically possible. A 1.43-k $\Omega$ , 1% resistor was chosen.

$$R_{IMON} = \frac{0.675 \text{ V} \times R_{SET}}{I_{LIM} \times R_{SENSE}}$$

therefore,

$$R_{IMON} = \frac{0.675 \text{ V} \times 51.1 \Omega}{12 \text{ A} \times 2 \text{ m}\Omega} = 1437 \Omega \tag{5}$$

**STEP 2. Choose MOSFET  $M_1$**

The next design step is to select  $M_1$ . The TPS24720 is designed to use an N-channel MOSFET with a gate-to-source voltage rating of 20 V.

Devices with lower gate-to-source voltage ratings can be used if a Zener diode is connected so as to limit the maximum gate-to-source voltage the transistor sees.

The next factor to consider is the drain-to-source voltage rating,  $V_{DS(MAX)}$ , of the MOSFET. Although the MOSFET only sees 12 V dc, it may experience much higher transient voltages during extreme conditions, such as the abrupt shutoff that occurs during a fast trip. A TVS may be required to limit inductive transients under such conditions. A transistor with a  $V_{DS(MAX)}$  rating of at least twice the nominal input power-supply voltage is recommended regardless of whether a TVS is used or not.

Next select the on-resistance of the transistor,  $r_{DS(on)}$ . The maximum on-resistance must not generate a voltage greater than the minimum power-good threshold voltage of 140 mV. Assuming a current limit of 12 A, a maximum  $r_{DS(on)}$  of 11.67 m $\Omega$  is required. Also consider the effect of  $r_{DS(on)}$  on the maximum operating temperature  $T_{J(MAX)}$  of the MOSFET. Equation 6 computes the value of  $r_{DS(on)(MAX)}$  at a junction temperature of  $T_{J(MAX)}$ . Most manufacturers list  $r_{DS(on)(MAX)}$  at 25°C and provide a derating curve from which values at other temperatures can be derived. Compute the maximum allowable on-resistance,  $r_{DS(on)(MAX)}$ , using Equation 6.

$$r_{DS(on)(MAX)} = \frac{T_{J(MAX)} - T_{A(MAX)}}{I_{MAX}^2 \times R_{\theta JA}},$$

therefore,

$$r_{DS(on)(MAX)} = \frac{150^\circ\text{C} - 50^\circ\text{C}}{(12\text{ A})^2 \times 51^\circ\text{C/W}} = 13.6\text{ m}\Omega \quad (6)$$

Taking these factors into consideration, the TI CSD16403Q5 was selected for this example. This transistor has a  $V_{GS(MAX)}$  rating of 16 V, a  $V_{DS(MAX)}$  rating of 25 V, and a maximum  $r_{DS(on)}$  of 2.8 m $\Omega$  at room temperature. During normal circuit operation, the MOSFET can have up to 10 A flowing through it. The power dissipation of the MOSFET equates to 0.24 W and an 9.6°C rise in junction temperature. This is well within the data sheet limits for the MOSFET. The power dissipated during a fault (e.g., output short) is far larger than the steady-state power. The power handling capability of the MOSFET must be checked during fault conditions.

### STEP 3. Choose Power-Limit Value, $P_{LIM}$ , and $R_{PROG}$

MOSFET  $M_1$  dissipates large amounts of power during inrush. The power limit  $P_{LIM}$  of the TPS24720 should be set to prevent the die temperature from exceeding a short-term maximum temperature,  $T_{J(MAX)2}$ . The short-term  $T_{J(MAX)2}$  could be set as high as 150°C while still leaving ample margin to the usual manufacturer's rating of 175°C. Equation 7 is an expression for calculating  $P_{LIM}$ ,

$$P_{LIM} \leq 0.8 \times \frac{T_{J(MAX)2} - \left[ \left( I_{MAX}^2 \times r_{DS(on)} \times R_{\theta CA} \right) + T_{A(MAX)} \right]}{R_{\theta JC}},$$

therefore,

$$P_{LIM} \leq 0.8 \times \frac{130^\circ\text{C} - \left[ \left( (12\text{ A})^2 \times 0.002\ \Omega \times (51^\circ\text{C/W} - 1.8^\circ\text{C/W}) \right) + 50^\circ\text{C} \right]}{1.8^\circ\text{C/W}} = 29.3\text{ W} \quad (7)$$

where  $R_{\theta JC}$  is the junction-to-case thermal resistance of the MOSFET,  $r_{DS(on)}$  is its resistance at the maximum operating temperature, and the factor of 0.8 represents the tolerance of the constant-power engine. For an ambient temperature of 50°C, the calculated maximum  $P_{LIM}$  is 29.3 W. From Equation 1, a 53.6-k $\Omega$ , 1% resistor is selected for  $R_{PROG}$  (see Equation 8).

$$R_{PROG} = \frac{3125}{P_{LIM} \times R_{SENSE}},$$

therefore,

$$R_{PROG} = \frac{3125}{29.3\text{ W} \times 0.002\ \Omega} = 53.15\text{ k}\Omega \quad (8)$$

### STEP 4. Choose Output Voltage Rising Time, $t_{ON}$ , and Timing Capacitor $C_T$

The maximum output voltage rise time,  $t_{ON}$ , set by timer capacitor  $C_T$  must suffice to fully charge the load capacitance  $C_{OUT}$  without triggering the fault circuitry. Equation 9 defines  $t_{ON}$  for two possible inrush cases. Assuming that only the load capacitance draws current during startup,

$$t_{ON} = \begin{cases} \frac{C_{OUT} \times P_{LIM}}{2 \times I_{LIM}^2} + \frac{C_{OUT} \times V_{VCC(MAX)}^2}{2 \times P_{LIM}} - \frac{C_{OUT} \times V_{VCC(MAX)}}{I_{LIM}} & \text{if } P_{LIM} < I_{LIM} \times V_{VCC(MAX)} \\ \frac{C_{OUT} \times V_{VCC(MAX)}}{I_{LIM}} & \text{if } P_{LIM} > I_{LIM} \times V_{VCC(MAX)} \end{cases}$$

therefore,

$$t_{ON} = \frac{470 \mu\text{F} \times 29.3 \text{ W}}{2 \times (12 \text{ A})^2} + \frac{470 \mu\text{F} \times (12 \text{ V})^2}{2 \times 29.3 \text{ W}} - \frac{470 \mu\text{F} \times 12 \text{ V}}{12 \text{ A}} = 0.614 \text{ ms} \quad (9)$$

The next step is to determine the minimum fault-timer period. In [Equation 9](#), the output rise time is  $t_{ON}$ . This is the amount of time it takes to charge the output capacitor up to the final output voltage. However, the fault timer uses the difference between the input voltage and the gate voltage to determine if the TPS24720 is still in inrush limit. The fault timer continues to run until  $V_{GS}$  rises 6 V (for  $V_{VCC} = 12 \text{ V}$ ) above the input voltage. Some additional time must be added to the charge time to account for this additional gate voltage rise. The minimum fault time can be calculated using [Equation 10](#),

$$t_{FLT} = t_{ON} + \frac{6 \text{ V} \times C_{ISS}}{I_{GATE}},$$

therefore,

$$t_{FLT} = 0.614 \text{ ms} + \frac{6 \text{ V} \times 2040 \text{ pF}}{20 \mu\text{A}} = 1.23 \text{ ms} \quad (10)$$

where  $C_{ISS}$  is the MOSFET input capacitance and  $I_{GATE}$  is the minimum gate sourcing current of TPS24720, or 20  $\mu\text{A}$ . Using the example parameters and the CSD16403Q5 data sheet in [Equation 10](#) leads to a minimum fault time of 1.23 ms. This time is derived considering the tolerances of  $C_{OUT}$ ,  $C_{ISS}$ ,  $I_{LIM}$ ,  $P_{LIM}$ ,  $I_{GATE}$ , and  $V_{VCC(MAX)}$ . The fault timer must be set to a value higher than 1.23 ms to avoid turning off during start-up, but lower than any maximum fault time limit determined by the device SOA curve.

There is a maximum time limit set by the SOA curve of the MOSFET. Referring to [Figure 38](#), which shows the CSD16403Q5 SOA curve at  $T_J = 25^\circ\text{C}$ , the MOSFET can tolerate 12 A with 12 V across it for approximately 20 ms. If the junction temperature  $T_J$  is other than  $25^\circ\text{C}$ , then the pulse time should be scaled by a factor of  $(150^\circ\text{C} - T_J) / (150^\circ\text{C} - 25^\circ\text{C})$ . Therefore, the fault timer should be set between 1.23 ms and 20 ms. For this example, we will select 7 ms to allow for variation of system parameters such as temperature, load, component tolerance, and input voltage. The timing capacitor is calculated in [Equation 11](#) as 52 nF. Selecting the next-highest standard value, 56 nF, yields a 7.56-ms fault time.

$$C_T = \frac{10 \mu\text{A}}{1.35 \text{ V}} \times t_{FLT},$$

therefore,

$$C_T = \frac{10 \mu\text{A}}{1.35 \text{ V}} \times 7 \text{ ms} = 52 \text{ nF} \quad (11)$$

Figure 38. CSD16403Q5 SOA Curve

### STEP 5. Calculate the Retry-Mode Duty Ratio

In retry mode, the TPS24720 is on for one charging cycle and off for 16 charge/discharge cycles, as can be seen in Figure 35. The first  $C_T$  charging cycle is from 0 V to 1.35 V, which gives 7.56 ms. The first  $C_T$  discharging cycle is from 1.35 V to 0.35 V, which gives 5.6 ms. Therefore, the total time is 7.56 ms + 33 x 5.6 ms = 192.36 ms. As a result, the retry mode duty ratio is 7.56 ms/192.36 ms = 3.93%.

### STEP 6. Select $R_1$ , $R_2$ , and $R_3$ for UV and OV

Next, select the values of the OV and UV resistors,  $R_1$ ,  $R_2$ , and  $R_3$ , as shown in the typical application diagram on the front page. From the TPS24720 electrical specifications,  $V_{OVTHRESH} = 1.35$  V and  $V_{ENTHRESH} = 1.35$  V.  $V_{OV}$  is the overvoltage trip voltage, which in this case is 14 V.  $V_{UV}$  is the undervoltage trip voltage, which for this example equals 10.8 V.

$$V_{ENTHRESH} = \frac{R_3}{R_1 + R_2 + R_3} \times V_{OV} \quad (12)$$

$$V_{UVTHRESH} = \frac{R_2 + R_3}{R_1 + R_2 + R_3} \times V_{UV} \quad (13)$$

Assume  $R_3$  is 1 k $\Omega$  and use Equation 12 to solve for  $(R_2 + R_3)$ . Use Equation 13 and the  $(R_2 + R_3)$  from Equation 12 to solve for  $R_2$  and finally for  $R_3$ . From Equation 12,  $(R_2 + R_3) = 9370.4 \Omega$ . From Equation 13,  $R_2 = 296 \Omega$  and  $R_1 = 9.074$  k $\Omega$ . Scaling all three resistors by a factor of ten to use less supply current for these voltage references and using standard 1% resistor values gives  $R_1 = 90.9$  k $\Omega$ ,  $R_2 = 2.94$  k $\Omega$ , and  $R_3 = 10$  k $\Omega$ .

### STEP 7. Choose $R_{GATE}$ , $R_4$ , $R_5$ , $R_6$ , and $C_1$

In the typical application diagram on the front page, the gate resistor,  $R_{GATE}$ , is intended to suppress high-frequency oscillations. A resistor of 10  $\Omega$  serves for most applications, but if  $M_1$  has a  $C_{ISS}$  below 200 pF, then 33  $\Omega$  is recommended. Applications with larger MOSFETs and very short wiring may not require  $R_{GATE}$ .  $R_4$ ,  $R_5$ , and  $R_6$  are required only if PGb, FLTb, and FFLTb are used; these resistors serve as pullups for the open-drain output drivers. The current sunk by each of these pins should not exceed 2 mA (referring to the RECOMMENDATION OPERATING CONDITIONS table).  $C_1$  is a bypass capacitor to help control transient voltages, unit emissions, and local supply noise while in the disabled state. Where acceptable, a value in the range of 0.001  $\mu$ F to 0.1  $\mu$ F is recommended.

### ALTERNATIVE DESIGN EXAMPLE: GATE CAPACITOR (dV/dt) CONTROL IN INRUSH MODE

The TPS24720 can be used in applications that expect a constant inrush current. This current is controlled by a capacitor connected from the GATE terminal to GND. A resistor of 1 k $\Omega$  placed in series with this capacitor prevents it from slowing a fast-turnoff event. In this mode of operation,  $M_1$  operates as a source follower, and the slew rate of the output voltage approximately equals the slew rate of the gate voltage (see Figure 39).

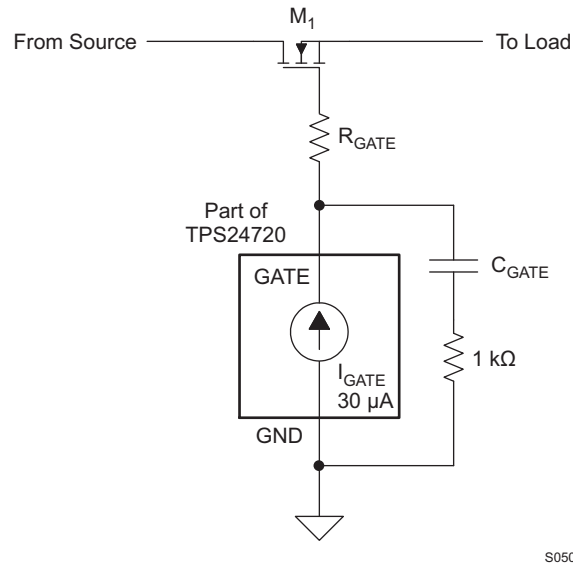

To implement a constant-inrush-current circuit, choose the time to charge,  $\Delta t$ , using Equation 14,

$$\Delta t = \frac{C_{OUT} \times V_{VCC}}{I_{CHG}} \quad (14)$$

where  $C_{OUT}$  is the output capacitance,  $V_{VCC}$  is the input voltage, and  $I_{CHG}$  is the desired charge current. Set  $P_{LIM}$  to a value greater than  $V_{VCC} \times I_{CHG}$  to prevent power limiting from affecting the desired current.

To select the gate capacitance use Equation 15.

$$C_{GATE} = \left( I_{GATE} \times \frac{\Delta t}{V_{VCC}} \right) - C_{ISS} \quad (15)$$

S0509-01

**Figure 39. Gate Capacitor (dV/dt) Control Inrush Mode.**

## ADDITIONAL DESIGN CONSIDERATIONS

### Use of PGB

Use the PGB pin to control and coordinate a downstream dc/dc converter. If this is not done, then a long time delay is needed to allow  $C_{OUT}$  to fully charge before the converter starts. An undesirable latch-up condition can be created between the TPS24720 output characteristic and the dc/dc converter input characteristic if the converter starts while  $C_{OUT}$  is still charging; using the PGB pin is one way to avoid this.

### Output Clamp Diode

Inductive loads on the output may drive the OUT pin below GND when the circuit is unplugged or during a current-limit event. The OUT pin ratings can be satisfied by connecting a diode from OUT to GND. The diode should be selected to control the negative voltage at the full short-circuit current. Schottky diodes are generally recommended for this application.

### Gate Clamp Diode

The TPS24720 has a relatively well-regulated gate voltage of 12 V–15.5 V with a supply voltage  $V_{VCC}$  higher than 4 V. A small clamp Zener from gate to source of  $M_1$  is recommended if  $V_{GS}$  of  $M_1$  is rated below 12 V. A series resistance of several hundred ohms or a series silicon diode is recommended to prevent the output capacitance from discharging through the gate driver to ground.

### High-Gate-Capacitance Applications

Gate voltage overstress and abnormally large fault-current spikes can be caused by large gate capacitance. An external gate clamp Zener diode is recommended to assist the internal Zener if the total gate capacitance of  $M_1$  exceeds about 4000 pF. When gate capacitor dV/dt control is used, a 1-kΩ resistor in series with  $C_{GATE}$  is recommended (see Figure 39). If the series R-C combination is used for MOSFETs with  $C_{ISS}$  less than 3000 pF, then a Zener is not necessary.

### Bypass Capacitors

It is a good practice to provide low-impedance ceramic capacitor bypassing of the VCC and OUT pins. Values in the range of 10 nF to 1  $\mu$ F are recommended. Some system topologies are insensitive to the values of these capacitors; however, some are not and require minimization of the value of the bypass capacitor. Input capacitance on a plug-in board may cause a large inrush current as the capacitor charges through the low-impedance power bus when inserted. This stresses the connector contacts and causes a short voltage sag on the input bus. Small amounts of capacitance (e.g., 10 nF to 0.1  $\mu$ F) are often tolerable in these systems.

### Output Short-Circuit Measurements

Repeatable short-circuit testing results are difficult to obtain. The many details of source bypassing, input leads, circuit layout and component selection, output shorting method, relative location of the short, and instrumentation all contribute to variation in results. The actual short itself exhibits a certain degree of randomness as it microscopically bounces and arcs. Care in configuration and methods must be used to obtain realistic results. Do not expect to see waveforms exactly like those in the data sheet; every setup differs.

### Layout Considerations

TPS24720 applications require careful attention to layout to ensure proper performance and to minimize susceptibility to transients and noise. In general, all traces should be as short as possible, but the following list deserves first consideration:

- Decoupling capacitors on VCC pin should have minimal trace lengths to the pin and to GND.
- Traces to SET and SENSE must be short and run side-by-side to maximize common-mode rejection. Kelvin connections should be used at the points of contact with  $R_{SENSE}$  (see Figure 40).
- SET runs must be short on both sides of  $R_{SET}$ .
- Power path connections should be as short as possible and sized to carry at least twice the full-load current, more if possible.
- Connections to GND and IMON pins should be minimized after the previously described connections have been placed.
- The device dissipates low power, so soldering the thermal pad to the board is not a requirement. However, doing so improves thermal performance and reduces susceptibility to noise.
- Protection devices such as snubbers, TVS, capacitors, or diodes should be placed physically close to the device they are intended to protect, and routed with short traces to reduce inductance. For example, the protection Schottky diode shown in the typical application diagram on the front page of the data sheet should be physically close to the OUT pin.

**PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish	MSL Peak Temp (3)	Op Temp (°C)	Top-Side Markings (4)	Samples
TPS24720RGT	PREVIEW	QFN	RGT	16		TBD	Call TI	Call TI	-40 to 85		
TPS24720RGTR	ACTIVE	QFN	RGT	16	3000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 85	24720	
TPS24720RGTT	ACTIVE	QFN	RGT	16	250	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	-40 to 85	24720	

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) Multiple Top-Side Markings will be inside parentheses. Only one Top-Side Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Top-Side Marking for that device.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

PLASTIC QUAD FLATPACK NO-LEAD

4203495/H 10/11

- NOTES:
- All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
  - This drawing is subject to change without notice.
  - Quad Flatpack, No-leads (QFN) package configuration.
  - The package thermal pad must be soldered to the board for thermal and mechanical performance.
  - See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
  - Falls within JEDEC MO-220.

# THERMAL PAD MECHANICAL DATA

RGT (S-PVQFN-N16)

PLASTIC QUAD FLATPACK NO-LEAD

## THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at [www.ti.com](http://www.ti.com).

The exposed thermal pad dimensions for this package are shown in the following illustration.

Exposed Thermal Pad Dimensions

NOTE: All linear dimensions are in millimeters

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
