LM2457

Monolithic Triple 7.5nS CRT Driver With Integrated Clamp and G1 Blanking

General Description

The LM2457 driver is an integrated high voltage triple CRT driver circuit designed for use in color monitor applications. The input signal interface to the IC is a multiplexed signal containing both clamp and video signal information, relative to an external 1.7 VDC reference.

The IC contains three high gain, differential input, high input impedance, wide band amplifiers which directly drive the RGB cathodes of a CRT. Each channel has its gain internally set to -52 and can drive CRT capacitive loads as well as resistive loads present in other applications, limited only by the package's power dissipation.

Integrated with the driver is a triple video clamp circuit for DC recovery of each of the AC coupled video outputs. The DC clamp circuit amplifies the clamp signal that is multiplexed on the video signal input. The DC clamp amplifiers are high gain, differential input, high input impedance amplifiers, setting a low impedance DC level at the clamp output which can be used to restore the DC level of the cathode drive. Each channel has a gain that is internally set to +75.

Also integrated within the package is a $43V_{\rm p-p}$ vertical blanking driver that is designed to drive the vertical retrace blanking signal to the G1. This is a current limited, low impedance output capable of driving normal G1 decoupling capacitances via an external resistor.

The output of the G1 driver can also be used to drive a voltage boost capacitor (22uF). When connected between the G1 drive output and the 120v supply input pin, a 120v boost supply is achieved which can be used to drive the internal DC clamp circuit, thereby eliminating the requirement for a 120V clamp supply.

The IC is packaged in an industry standard 15 lead TO-220 molded plastic power package.

Features

- 7.5ns low power driver
- Three integrated active clamp circuits
- Integrated 120V supply and G1 vertical blank drive circuit
- Multiplexed signal interface to LM125X OSD Pre-amp minimizes pin count while increasing functionality
- External System voltage reference
- Convenient TO-220 staggered lead package

Recommended Applications

- 1024 x 768 Resolution displays up to 85Hz refresh
- Pixel clock frequencies up to 95MHz
- Monitor requiring horizontal video blanking

Special Features

MULTIPLEXED VIDEO SIGNAL INPUT

The LM2457 accepts the multiplexed video signal from the LM1253 which contains the video signal and DC clamp level. This multiplexed signal is shown in *Figure 3*. It was designed to simplify the interface between the pre-amp and CRT

Driver. Slightly over 1V of dynamic range is provided for the video and OSD portions of the waveform. The clamp signal control voltage range is approximately 0.9V. The typical numbers for the black and white levels shown correspond to a nominal swing of $40\mathrm{V}_{\mathrm{P-P}}$ at the video outputs of the LM2457.

Note 1: Limits of "Absolute Maximum Ratings" indicate limits below which damage to the device will not occur.

Note 2: Limits of "Operating Ratings" indicate required boundaries of conditions for which the device is functional, but is not guaranteed to meet specific performance

Note 3: All voltages are measured with respect to GND, unless otherwise specified.

Note 4: Linearity error is the variation in DC gain from $V_{IN} = 2.0V$ to 3.0V.

Note 5: Input from signal generator: t_r , $t_f < 1$ ns.

Driver Test Circuit

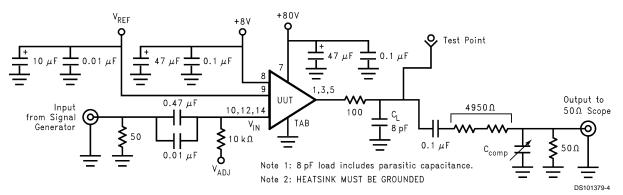

FIGURE 4. Test Circuit (One Channel)

Figure 4 shows the test circuit for the LM2457. This circuit allows testing of the LM2457 in a 50Ω environment as well as with a FET probe. The 4950Ω resistor at the output forms a 200:1 voltage divider when connected to a 50Ω load. C_{COMP} is used to flatten the frequency response of the 200:1 divider. Performance will be affected slightly by the 5K load.

Typical Performance Characteristics

(Unless otherwise noted: V_{CC} = $80V_{DC}$, V_{BB} = $8V_{DC}$, C_L = 8pF, T_C = $50^{\circ}C$.

120V Boost/G1 Drive Test Circuit

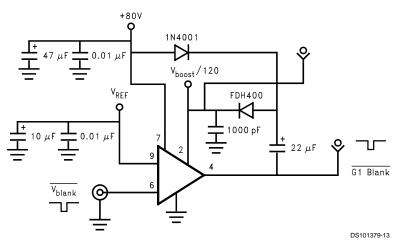

FIGURE 13. 120V Boost/G1 Drive Test Circuit

Theory of Operation

The LM2457 is a high voltage monolithic three channel CRT driver and three-channel DC clamp circuit suitable for high-resolution display applications. The device also contains a G1 blanking signal driver, which also can be used to generate a 120 VDC supply to power the DC clamp circuit. The LM2457 operates using 80V and 8V power supplies. An external supply can also be used to power the clamp circuit if the user desires to do so. The part is housed in the industry standard 15-lead TO-220 molded plastic power package.

A simplified circuit block diagram of the LM2457 is shown in Figure 1. A reference supply of approximately 1.7 VDC is supplied to pin 9 of the device. This provides a reference level for the minus input of the video and clamp buffer amplifiers as well as for the vertical blank comparator. The output of the buffer amplifier drives the video amplifier which provides a gain of -52 to the input signal and only amplifies the portion of the input signal that is above the reference voltage. When the input signal is at or below $V_{\rm REF}$ the video outputs are driven to the +80V supply rail. The output of the driver is a low impedance complimentary emitter follower circuit that minimizes the effect of capacitive load variations on transient response.

The clamp amplifier provides a gain of 75 and only amplifies the portion of the input signal that is below the reference voltage. When the input signal is at or above V_{REF} the clamp outputs are driven to the V_{boost} /120V supply rail. The vertical blank comparator drives the boost circuit, which generates a $43V_{D-D}$ signal that can directly drive typical G1 capacitive

loads. When the first vertical blanking pulse is received, the G1 drive output enters a current limited latched state until the 120V boost capacitor is fully charged. Thereafter, the G1 output pulses in response to the vertical blanking pulse received on the multiplexed V_{REF} signal line.

Figures 4, 11, 13 show the typical test circuits for evaluation of the LM2457.

Application Hints

INTRODUCTION

National Semiconductor (NSC) is committed to provide application information that assists our customers in obtaining the best performance possible from our products. The following information is provided in order to support this commitment. The reader should be aware that the optimization of performance was done using a specific printed circuit board designed at NSC. Variations in performance can be realized due to physical changes in the printed circuit board and the application. Therefore, the designer should know that component value changes might be required in order to optimize performance in a given application. The values shown in this document can be used as a starting point for evaluation purposes. When working with high bandwidth circuits, good layout practices are always critical to achieving maximum performance.

IMPORTANT INFORMATION

The LM2457 performance is targeted for monitor applications with pixel clock frequencies up to 95MHz. It is a part of the AC2DC new product family that is being developed by National Semiconductor. Since this device is significantly different from all our previous CRT drivers, it is very important to read all the application information supplied in this document. Should you have additional questions, please contact your local FAE or sales office.

Please refer to the NSC neck board schematic and layout that are shown in *Figures 17, 18, 19* during the following discussion.

POWER SUPPLY BYPASS

Since the LM2457 is a high bandwidth amplifier, proper power supply bypassing is critical for optimum performance. Improper power supply bypassing can result in large overshoot, ringing or oscillation.

 V_{CC} *Bypassing*—A 0.1 μF (C48) capacitor should be connected from the V_{CC} supply pin (7) to ground, as close to the supply pin and heatsink (device tab) ground point as possible. Additionally, a 47 μF electrolytic capacitor (C39) should be connected through a ferrite bead (FB2 in the schematic) to the supply pin and ground. A Fair-Rite 2743003112-TR (100 Ω @ 100 MHz) or equivalent should be used.

 \emph{V}_{BB} *Bypassing*—A 0.1 μF (C8) capacitor should be connected from the V_{BB} supply to ground, as close as possible to the device with as short as possible connections. Additionally, a 47 μF electrolytic capacitor (C21) should be connected through a ferrite bead (FB1) to the supply pin and ground. A Fair-Rite 2743003112-TR (100 Ω @ 100 MHz) or equivalent should be used.

REFERENCE VOLTAGE

The LM2457 receives a reference voltage from the LM1253A preamp. It is critical that a 0.1 μF bypass cap be added from the V_{REF} pin to ground. The ground connection should be as close as possible to the video input side of the device (see C30 in Figure 18). A 300Ω resistor should also be used between the V_{REF} pin of the LM2457 and the V_{REF} pin of the LM1253A. V_{REF} should also be bypassed close to the preamp.

THE VIDEO APPLICATION CIRCUIT

Figure 14 shows the recommended circuit topology for the video amplifiers in the LM2457. This circuit is designed to yield the best transient response and reduce radiated emissions while also protecting the amplifier from damage that can be caused by CRT Arcs. The schematic in Figures 17, 18 shows the values that yielded best performance in the NSC reference design board. The following sections discuss arc protection and transient response in detail. Refer to Figures 17, 18, 19 for the full application schematic and PCB layout.

ARC Protection

During normal CRT operation, internal arcing may occasionally occur. At the beginning of an arc event there is some very high frequency ringing (@ ~ 100 MHz). Spark gaps, in the range of 200V, connected from the CRT cathodes to CRT ground will limit the maximum voltage, but to a value that is much higher than allowable on the LM2457. They are also ineffective at limiting the peak voltage of the initial high frequency burst. This fast, high voltage, high energy pulse

can damage the LM2457 video output stages. The application circuit shown in Figure 14 is designed to help clamp the voltage at the output of the LM2457 to a safe level. The clamp diodes should have a fast transient response, high peak current rating, low series impedance and low shunt capacitance. FDH400 or equivalent diodes are recommended. D1 and D2 should have short, low impedance connections to V_{CC} and ground respectively. The cathode of D1 should be located very close to a separately decoupled bypass capacitor (C3 in Figure 14). The ground connection of the diode and the decoupling capacitor should be very close to the LM2457 ground and should be of as low impedance as possible. This will significantly reduce the high frequency voltage transients that the LM2457 would be subjected to during an arcover condition. Resistor R2 limits the arcover current that is seen by the diodes while R1 limits the current into the LM2457 as well as the voltage stress at the video outputs of the device. R2 should be a 1/2W solid carbon type resistor. R1 can be a 1/4W metal or carbon film type resistor. Inductor L1 is critical to reduce the initial high frequency voltage levels that the LM2457 would be subjected to. Having large value resistors for R1 and R2 would be desirable, but this has the effect of increasing rise and fall times. The inductor will not only help protect the device but it will also help optimize rise and fall times as well as minimize EMI. For proper arc protection, it is important to not omit any of the arc protection components shown in Figure 14. Omitting any of these components could cause serious reliability problems in production.

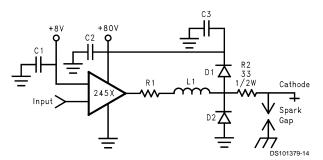

FIGURE 14. One Video Channel of the LM2457 with the Recommended Application Circuit

Optimizing Transient Response

Referring to Figure 14, there are three components (R1, R2 and L1) that can be adjusted to optimize the transient response of the application circuit. Increasing the values of R1 and R2 will slow the circuit down while decreasing overshoot. Increasing the value of L1 will speed up the circuit as well as increase overshoot. It is very important to use inductors with very high self-resonant frequencies, preferably above 300 MHz. Ferrite core inductors from J.W. Miller Magnetics (part # 78FXXXM, where XXX specifies the value) were used for optimizing the performance of the device in the NSC application board. The values shown in Figure 18 exhibited the best overall performance in a 17 inch monitor in our lab. These can be used as a good starting point for the evaluation of the LM2457 in a new monitor application. Using a variable resistor for R1 in series with a fixed value inductor is a great way to help dial in the values needed for optimum performance in a given application. Once the optimum values are determined the variable resistors can be replaced with fixed values and corresponding inductor can be installed. In addition to the output circuit, a series inductor is used between the LM1253A video outputs and the LM2457 inputs.

Effect of Load Capacitance

Figure 10 shows the effect of increased load capacitance on the speed of the device. This demonstrates the importance of knowing the load capacitance in the application. It is important to note that the rise time of the series R in the test circuit in Figure 4 along with the load capacitance will increase its contribution to the speed degradation as the load capacitance is increased. The previous section discussed how to optimize the transient response in the application with the use of a series inductor.

Effect of Offset

Figure 9 shows the variation in rise and fall times when the output offset of the device is varied from 40 VDC to 50 VDC. The rise time shows a maximum variation relative to the center data point (45 VDC) of less than 6%. The fall time shows a variation of about 6% relative to the center data point.

It is recommended that the video black level be set about 10V below the $\rm V_{CC}$ power supply in the application (Black level at ~70 with $\rm V_{CC}$ = 80 $\rm V_{DC}$). This will give the best overall performance while also minimizing the DC power dissipation.

DC CLAMP AMPLIFIERS

The portion of the multiplexed input signal that is below the reference voltage controls the DC clamp amplifiers. The DC transfer function of the amplifier is shown in *Figure 12*. *Figure 15* shows the application circuit for the clamp amplifier. Clamp diode D1 is placed as close as possible to the video node to minimize trace lengths and parasitic capacitance. Pull-up resistor R1 is required to bias the PNP output stage of the clamp circuit. Capacitor C2 provides a low impedance at high frequencies and helps minimize clamp level variation that could be caused by changes in the cathode current.

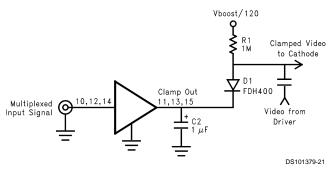

FIGURE 15. Clamp Application Circuit.

INTEGRATED BOOST SUPPLY AND G1 BLANK CIRCUIT

Upon initial power up the G1 V_{blank} /Cap Low input will sink current until the boost capacitor is charged up to approximately 43V (V_{CC1} – V_{G1-L}). After this initial charge up period, the voltage across the boost capacitor will be replenished during the vertical blank interval.

The charge cycle will be initiated by the V_{blank} input signal (negative going, logic level pulse). Figure 16 shows the boost application circuit. During the charge cycle the voltage at pin 4 will be set to ~36V and capacitor C28 will be charged to ~43V through diode D11. When the charge cycle is com-

pleted, the voltage at pin 4 will be set to \sim 79V and the plus side of the boost cap will be at \sim 122V $_{DC}$. The pin 2 side of capacitor C29 will then be charged to \sim 121.3V (0.7V below 122) through D12. Diode D12 is required to avoid turning on the ESD protection diodes between the video clamp outputs and the 120V pin during the charge cycle. C29 is required to maintain the 120V at pin 2 during the charge cycle.

The 43Vp-p pulse at pin 4 can be ac-coupled to G1 of the CRT to blank the CRT during vertical retrace. The recommended application circuit for doing this is shown in *Figure* 18

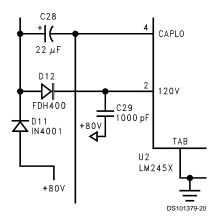

FIGURE 16. Boost Circuit Schematic

THERMAL CONSIDERATIONS

Figure 6 shows the performance of the LM2457 video amplifiers in the test circuit shown in Figure 4 as a function of case temperature. The figure shows that the rise time of the LM2457 decreases by approximately 4% as the case temperature increases from 50°C to 100°C. This corresponds to a speed degradation of <1% for every 10°C rise in case temperature. There is a negligible change in fall time versus temperature in the test circuit.

Figure 8 shows the total power dissipation of the LM2457 vs. frequency when all three video channels of the device are driving an 8 pF or 12pF load with a $40V_{p-p}$ signal. The graph assumes a 72% active time (device operating at the specified frequency) which is typical in a monitor application. The other 28% of the time the device is assumed to be sitting at the black level (65V in this case). This graph gives the designer the information needed to determine the heat sink requirement for his application. It is important to note that the capacitive load dramatically effects the AC component of the total power dissipation.

The LM2457 case temperature must be maintained below 100°C. If the maximum expected ambient temperature is 50°C and the maximum power dissipation is 8.5W, then a maximum heat sink thermal resistance can be calculated:

$$R_{HS} = \frac{100 \text{ °C} - 50 \text{ °C}}{8.5 \text{ W}} = 5.9 \text{ °C Per Watt}$$

This example assumes a capacitive load of 8 pF, no resistive load and a maximum operating frequency of 50 MHz or greater.

THE NSC REFERENCE DESIGN

Figures 17, 18, 19 show the schematic and layout for the NSC Neck Board Reference Design. It contains a complete video channel from monitor input to CRT cathode. Performance is ideal for 1024 X 768 resolution displays with pixel

clock frequencies up to 95MHz. A sample of this design along with all necessary support hardware and materials can be obtained from your local sales office.

PC Board Layout Considerations

For optimum performance, an adequate ground plane, isolation between channels, good supply bypassing and minimizing unwanted feedback are necessary. Also, the length of the signal traces from the preamplifier to the LM2457 and from the LM2457 to the CRT cathode should be as short as possible.

Due to the high gain and bandwidth of the LM2457, the part may oscillate in a monitor if feedback occurs around the video channel through the chassis wiring. To prevent this, leads to the video amplifier input circuit should be shielded, and input circuit wiring should be spaced as far as possible from output circuit wiring.

IMPORTANT LAYOUT CONSIDERATIONS

The NSC reference design can be used directly or it can be used as a guide for future layouts. Note the location of the following components:

- C48—V_{CC} bypass capacitor, located very close to pin 7 and the device ground.
- C8—V_{BB} bypass capacitor, located close to pin 8 and ground.

- C34,C35, C46—V_{CC} bypass capacitors, near LM2457 V_{CC} clamp diodes. Very important for arc protection. Note the direct path from the capacitor ground to the LM2457 ground.
- C25-27—clamp output bypass caps. Very important for a stable DC clamp voltage and for protecting the clamp outputs from damage due to a CRT arc.

The routing of the LM2457 video outputs to the CRT is very critical to achieving optimum performance. Figure 20 shows the routing and component placement from pin 1 of the LM2457 to the blue cathode. Note that the components are placed so that they almost line up from the output pin of the LM2457 to the blue cathode pin of the CRT connector. This is done to minimize the length of the video path between these two components. Note also that D16, D17, R17 and D7 are placed to minimize the size of the video nodes that they are attached to. This minimizes parasitic capacitance in the video path and also enhances the effectiveness of the protection diodes. The anode of protection diode D17 is connected directly to a section of the ground plane that has a short and direct path to the LM2457 ground pins. The cathode of D16 is connected to V_{CC} very close to decoupling capacitor C34, which is connected to the same section of the ground plane as D17. The diode placement and routing is very important for minimizing the voltage stress on the LM2457 video outputs during an arc over event. Lastly, notice that S1 is placed very close to the blue cathode and is tied directly to the ground under the CRT connector.

Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
