

DP83266

DP83266 MACSI(TM) Device (FDDI Media Access Controller and System Interface)

Literature Number: SNOS672A

DP83266 MACSI™ Device (FDDI Media Access Controller and System Interface)

General Description

The DP83266 Media Access Controller and System Interface (MACSI) implements the ANSI X3T9.5 Standard Media Access Control (MAC) protocol for operation in an FDDI token ring and provides a comprehensive System Interface.

The MACSI device transmits, receives, repeats, and strips tokens and frames. It produces and consumes optimized data structures for efficient data transfer. Full duplex architecture with through parity allows diagnostic transmission and self testing for error isolation and point-to-point connections.

The MACSI device includes the functionality of both the DP83261 BMACTM device and the DP83265 BSI-2TM device with additional enhancements for higher performance and reliability.

Features

- Over 9 kBytes of on-chip FIFO
- 5 DMA channels (2 Output and 3 Input)
- 12.5 MHz to 25 MHz operation
- Full duplex operation with through parity
- Supports JTAG boundary scan
- Real-time Void stripping indicator for bridges

- On-chip address bit swapping capability
- 32-bit wide Address/Data path with byte parity
- Programmable transfer burst sizes of 4 or 8 32-bit words
- Receive frame filtering services
- Frame-per-Page mode controllable on each DMA channel
- Demultiplexed Addresses supported on ABus
- New multicast address matching feature
- ANSI X3T9.5 MAC standard defined ring service options
- Supports all FDDI Ring Scheduling Classes (Synchronous, Asynchronous, etc.)
- Supports Individual, Group, Short, Long and External Addressing
- Generates Beacon, Claim, and Void frames
- Extensive ring and station statistics gathering
- Extensions for MAC level bridging
- Enhanced SBus compatibility
- Interfaces to DRAMs or directly to system bus
- Supports frame Header/Info splitting
- Programmable Big or Little Endian alignment

1.0 FDDI Chip Set Overview

National Semiconductor's FDDI chip set is shown in *Figure 1-1*. For more information about the PLAYER+™ device, consult the appropriate datasheet and application notes.

DP83256/56-AP/57 PLAYER+ Device Physical Layer Controller

The PLAYER+ device implements the Physical Layer (PHY) protocol as defined by the ANSI FDDI PHY X3T9.5 Standard along with all the necessary clock recovery and clock generation functions.

Features

- Single chip FDDI Physical Layer (PHY) solution
- Integrated Digital Clock Recovery Module provides enhanced tracking and greater lock acquisition range
- Integrated Clock Generation Module provides all necessary clock signals for an FDDI system from an external 12.5 MHz reference
- Alternate PMD Interface (DP83256-AP/57) Supports UTP twisted pair FDDI PMDS with no external clock recovery or clock generations functions required
- No External Filter Components
- Connection Management (CMT) Support (LEM, TNE, PC_React, CF_React, Auto Scrubbing)
- Full on-chip configuration switch
- Low Power CMOS-BIPOLAR design using a single 5V supply
- Full duplex operation with through parity
- Separate management interface (Control Bus)
- Selectable Parity on PHY-MAC Interface and Control Bus Interface
- Two levels of on-chip loopback
- 4B/5B encoder/decoder
- Framing logic
- Elasticity Buffer, Repeat Filter, and Smoother
- Line state detector/generator
- Supports single attach stations, dual attach stations and concentrators with no external logic
- DP83256/56-AP for SAS/DAS single path stations
- DP83257 for SAS/DAS single/dual path stations

In addition, the DP83257 contains an additional PHY_Data.request and PHY_Data.indicate port required for concentrators and dual attach stations.

DP83266 MACSI Device Media Access Controller and System Interface

The MACSI device implements the Timed Token Media Access Control protocol defined by the ANSI FDDI X3T9.5 MAC Standard as well as a high performance system interface.

Features

- Over 9 kBytes of on-chip FIFO
- 5 DMA channels (2 Output and 3 Input)
- 12.5 MHz to 25 MHz operation
- Full duplex operation with through parity
- Supports JTAG boundary scan
- Real-time Void stripping indicator for bridges
- On-chip address bit swapping capability
- 32-bit wide Address/Data path with byte parity
- Programmable transfer burst sizes of 4 or 8 32-bit words
- Receive frame filtering services
- Frame-per-Page mode controllable on each DMA channel
- Demultiplexed Addresses supported on ABus
- New multicast address matching feature
- ANSI X3T9.5 MAC standard defined ring service options
- Supports all FDDI Ring Scheduling Classes (Synchronous, Asynchronous, etc.)
- Supports Individual, Group, Short, Long and External Addressing
- Generates Beacon, Claim, and Void frames
- Extensive ring and station statistics gathering
- Extensions for MAC level bridging
- Enhanced SBus compatibility
- Interfaces to DRAMs or directly to system bus
- Supports frame Header/Info splitting
- Programmable Big or Little Endian alignment

2.0 General Features

The DP83266 MACSI device is a highly integrated FDDI controller. Together with the DP83256/57 PLAYER+ device, it forms a full-featured, high performance FDDI chip set useful for designing end station attachments, concentrators, bridges, routers, and other FDDI connections. The MACSI device provides all of the features and services of both the DP83261 BMAC device and the DP83265 BSI-2 device with enhanced performance and reliability.

For system connection, the MACSI device provides a simple yet powerful bus interface and memory management scheme to maximize system efficiency and it is capable of interfacing to a variety of host buses/environments. The MACSI device provides a 32-bit wide data interface, which can be configured to share a system bus to main memory or to use external shared memory. Also provided are 28-bit addresses multiplexed on the data pins as well as demultiplexed on dedicated pins. The system interface supports virtual addressing using fixed-size pages.

For network connection, the MACSI device provides many services which simplify network management and increase system performance and reliability. The MACSI device is capable of batching confirmation and indication status, filtering MAC frames with the same Information field as well as Void frames, and performing network monitoring functions.

2.1 FDDI MAC SUPPORT

The MACSI device implements the ANSI X3T9.5 FDDI MAC standard protocol for transmitting, receiving, repeating and stripping frames. The MACSI device provides all of the information necessary to implement the service primitives defined in the standard.

2.2 MAC ADDRESSING SUPPORT

Both long (48-bit) and short (16-bit) addressing are supported simultaneously, for both Individual and Group addresses.

2.3 MAC BRIDGING SUPPORT

Several features are provided to increase performance in bridging applications.

On the receive side, external address matching logic can be used to examine the PH_Indicate byte stream to decide whether to copy a frame, how to set the control indicators and how to increment the counters.

On the transmit side, transparency options are provided on the Source Address, the most significant bit of the Source Address, and the Frame Check Sequence (FCS).

In addition, support for an alternate stripping mechanism (implemented using My_Void frames) provides maximum flexibility in the generation of frames by allowing the use of Source Address Transparency (SAT).

2.4 MAC SERVICE CLASS SUPPORT

All FDDI MAC service classes are supported by the MACSI device including Synchronous, Asynchronous, Restricted Asynchronous, and Immediate service classes.

For Synchronous transmission, one or more frames are transmitted in accordance with the station's synchronous bandwidth allocation.

For Asynchronous transmission, one programmable asynchronous priority threshold is supported in addition to the threshold at the Negotiated Target Token Rotation time.

For Restricted Asynchronous transmission, support is provided to begin, continue and end restricted dialogues.

For Immediate transmissions, support is provided to send frames from either the Data, Beacon or Claim states and either ignore or respond to the received byte stream. After an immediate transmission a token may optionally be issued.

2.5 DIAGNOSTIC COUNTERS

The MACSI device includes a number of diagnostic counters and timers that monitor ring and station performance.

These counters allow measurement of the following:

- Number of frames transmitted and received by the station
- Number of frames copied as well as frames not copied
- Frame error rate of an incoming physical connection to the MAC
- Load on the ring based on the number of tokens received and the ring latency
- Ring latency
- Lost frames

The size of these counters has been selected to keep the frequency of overflow small, even under worst case operating conditions.

2.6 MANAGEMENT SERVICES

The MACSI device provides management services to the Host System via the Control Bus Interface. This interface allows access to internal registers to control and configure the MACSI device.

2.7 RING PARAMETER TUNING

The MACSI device includes settable parameters to allow tuning of the network to increase performance over a large range of network sizes.

The MACSI device supports systems of two stations with little cable between them to ring configurations much larger than the 1000 physical attachments and/or 200 kilometer distance that are specified as the default values in the standard.

The MACSI device also handles frames larger than the 4500 byte default maximum frame size as specified in the standard.

2.8 MULTI-FRAME STREAMING INTERFACE

The MACSI device provides an interface to support multi-frame streaming. Multiple frames can be transmitted after a token is captured within the limits of the token timer thresholds.

2.9 BEACON, CLAIM, AND VOID FRAMES GENERATION

For purposes of transient token and ring recovery, no processor intervention is required. The MACSI device automatically generates the appropriate MAC frames.

2.10 SELF TESTING

Since the MACSI device has a full duplex architecture, loopback testing is possible before entering the ring and during normal ring operation.

There are several possible loopback paths:

- Internal to the MACSI device
- Through the PLAYER+ device(s) using the PLAYER+ configuration switch
- Through the PLAYER+ Clock Recovery Module.

2.0 General Features (Continued)

These paths allow error isolation at the device level.

The MACSI device also supports through parity. Even when parity is not used by the system, parity support can be provided across the PHY Interface.

2.11 32-BIT ADDRESS/DATA PATH TO HOST MEMORY

The MACSI device provides a 32-bit wide synchronous data interface, which permits connection to a standard multi-master system bus operating from 12.5 MHz to 33 MHz, or to local memory, using Big or Little Endian byte ordering. Demultiplexed addresses are provided on dedicated pins. Address information is also multiplexed on the data pins to provide backward compatibility for designs based on the BSI device. The local memory may be static or dynamic. For maximum performance, the MACSI device uses burst mode transfers, with four or eight 32-bit words to a burst. To assist the user with the burst transfer capability, the three bits of the address which cycle during a burst are output as demultiplexed signals. Maximum burst speed is one 32-bit word per clock, but slower speeds may be accommodated by inserting wait states.

The MACSI device can operate within any combination of cached, non-cached, paged or non-paged memory environments. To provide this capability, all data structures are contained within a page boundary, and bus transactions never cross page boundaries. The MACSI device performs all bus transactions within aligned blocks to ease the interface to a cached environment.

2.12 MULTI-CHANNEL ARCHITECTURE

The MACSI device provides three Input Channels and two Output Channels, which are designed to operate independently and concurrently. They are separately configured by the user to manage the reception or transmission of a particular kind of frame (for example, synchronous frames only).

2.13 SUPPORT FOR HEADER/INFO SPLITTING

In order to support high performance protocol processing, the MACSI device can be programmed to split the header and information portions of (non-MAC/SMT) frames between two Indicate Channels. Frame bytes from the Frame Control field (FC) up to the user-defined header length are copied onto Indicate Channel 1, and the remaining bytes (Info) are copied onto Indicate Channel 2. This is useful for separating protocol headers from data and allows them to be stored in different regions of memory to prevent unnecessary copying. In addition, a protocol monitor application may decide to copy only the header portion of each frame.

2.14 MAC BRIDGING SUPPORT

Support for bridging and monitoring applications is provided by the Internal/External Sorting Mode. All frames matching the external address (frames requiring bridging) are sorted onto Indicate Channel 2, MAC and SMT frames matching the internal (Ring Engine) address are sorted onto Indicate Channel 0, and all other frames matching the device's internal address (short or long) are sorted onto Indicate Channel 1.

2.15 ADDRESS BIT SWAPPING

The MACSI contains the necessary logic for swapping the address fields within each frame between FDDI and IEEE Canonical bit order. This involves a bit reversal within each byte of the address field (e.g., 08-00-17-C2-A1-03 would be-

come 10:00:E8:43:85:C0). This option is selectable on a per channel basis and is supported on all transmit and receive channels. This is useful for bridging FDDI to Ethernet or for swapping addresses for higher level protocols.

2.16 STATUS BATCHING SERVICES

The MACSI device provides status for transmitted and received frames. Interrupts to the host are generated only at status breakpoints, which are defined by the user on a per DMA Channel basis. Breakpoints are selected when the Channel is configured for operation. To allow batching, the MACSI provides a status option called Tend, that causes the device to generate a single Confirmation Message Descriptor (CNF) for one or more Request Descriptors (REQs).

The MACSI device further reduces host processing time by separating received frame status from the received data. This allows the CPU to scan quickly for errors when deciding whether further processing should be done on received frames. If status was embedded in the data stream, all data would need to be read contiguously to find the Status Indicator.

2.17 RECEIVE FRAME FILTERING SERVICES

To increase performance and reliability, the MACSI device can be programmed to filter out identical MAC (same FC and Info field) or SMT frames received from the ring. Void frames are filtered out automatically. Filtering unnecessary frames reduces the fill rate of the Indicate FIFO, reduces CPU frame processing time, and reduces memory bus transactions.

2.18 TWO TIMING DOMAINS

To provide maximum performance and system flexibility, the MACSI device uses two independent clocks, one for the MAC (ring) Interface, and one for the system/memory bus. The MACSI device provides a fully synchronized interface between these two timing domains.

2.19 CLUSTERED INTERRUPTS

The MACSI device can be operated in a polled or interrupt-driven environment. The MACSI device provides the ability to generate attentions (interrupts) at group boundaries. Some boundaries are pre-defined in hardware; others are defined by the user when the Channel is configured. This interrupt scheme significantly reduces the number of interrupts to the host, thus reducing host processing overhead.

2.20 FIFO MEMORY

The MACSI device contains over 9 kBytes of on-chip FIFO memory. This memory includes separate 4.6 kByte FIFOs for both the Transmit (Request) and Receive (Indicate) data paths. These data FIFOs allow the MACSI device to support over 370 μ s of bus latency for both transmit and receive. They also allow the MACSI device to buffer entire maximum length FDDI frames on-chip for both transmit and receive simultaneously. This allows lower cost systems by enabling the MACSI device to reside directly on system buses with high latency requirements.

These FIFOs support all of the features available in the original BSI device including two transmit and three receive channels to make efficient use of the FIFO resources. New transmit thresholds are available to allow full use of the larger transmit FIFO.

2.0 General Features (Continued)

In addition to the 4.6 kByte data FIFOs, both the transmit and receive data paths contain Burst FIFO Blocks, each of which are organized as two banks of eight 32-bit words.

2.21 FRAME-PER-PAGE-PER-CHANNEL

The MACSI device has a feature which allows control of the Frame-per-Page mode (available on the BSI device) on a per-Channel basis. For example, this is useful in systems where Frame-per-Page mode is used to speed up memory space reclamation on an LLC channel, but where packing multiple frames into each page is desired to save space on the SMT channel.

2.22 COPY ALL MULTICAST

The MACSI provides a copy mode which allows all frames which are addressed with multicast addresses to be copied. Multicast addresses are those that have the Individual/Group address bit (most significant bit of the FDDI address) set. This simple scheme allows flexibility in the use of multicast addresses. The MACSI device copies all multicast frames and software makes the final determination as to which multicast groups this station belongs to.

2.23 BRIDGE STRIPPING INFORMATION

The MACSI device provides an output designed to make it easier to build transparent bridges. Source Address Transparency features are provided as well as features to allow these frames to be stripped from the ring. For transparent bridges, it is important to know when the MACSI is using this stripping feature to remove frames from the ring which were forwarded by this bridge but with an unknown source address, (i.e., Source Address Transparency enabled). This is important because the bridge does not want to "learn" these addresses. This feature is provided by the MACSI in the form of an output pin indicating which frames contain addresses which should be added to the address filter table (i.e. learned).

2.24 LED STATUS CONTROL OUTPUTS

The MACSI device (revision D and later) provides two outputs that give Transmit and Receive status information useful for controlling LEDs. The MACSI asserts the TXLED pin each time that it detects that the Request State machine has entered the "sending" state, (once per transmitted frame). Note that it will not assert TXLED for internally generated MAC frames. It asserts the RXLED pin each time it detects the End Delimiter of a copied frame (VCOPY and EDRCVD). Both of these pins use Open Drain output structures (this preserves pin compatibility with MACSI devices prior to revision D). Therefore, they require pull-up resistors when used for LED control information. To increase the LED on-time for visibility, the User must supply one-shot circuits triggered by TXLED and RXLED.

2.25 JTAG BOUNDARY SCAN

The MACSI device supports the JTAG boundary scan standard (IEEE Std. 1149.1-1990).

3.0 Architectural Description

The MACSI is derived from the BMAC and BSI devices. The MACSI is composed of the Ring Engine, the Service Engine, and the Bus Interface Unit. The Ring Engine performs the FDDI MAC Timed token protocol and contains the MAC transmitter and receiver. The Service Engine implements the Request and Indicate Data Services and contains the Transmit and Receive Data FIFOs. The Bus Interface Unit implements the high speed synchronous bus handshake and contains the Burst FIFOs.

The MACSI device uses a full duplex architecture and provides sufficient bandwidth at the ABUS for full duplex transmission with support for through parity. *Figure 3-1* shows the MACSI device architecture.

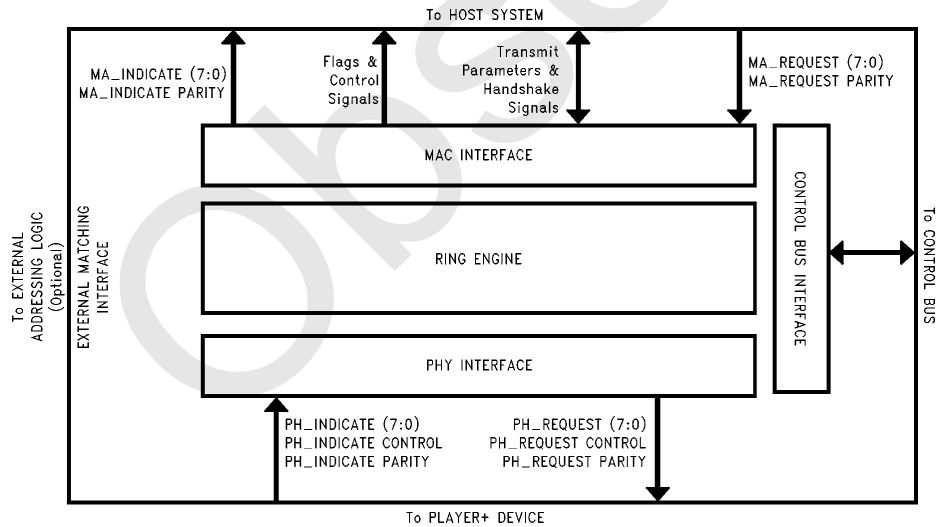

FIGURE 3-1. MACSI Device Block Diagram

TL/F/11705-2

3.0 Architectural Description (Continued)

3.1 INTERFACES

3.1.1 PHY Interface

The PHY Interface is a synchronous interface that provides a byte stream to the PLAYER+ device (the PHY Request byte stream, PHY_Request), and receives a byte stream from the PLAYER+ device (the PHY Indicate byte stream, PHY_Indicate).

The 10 bits transferred in both directions across the PH_Indicate and PH_Request Interfaces consists of one parity bit (odd parity), one control bit, and 8 bits of data. The control bit determines if the 8 data bits are a data symbol pair or a control symbol pair.

3.1.2 ABus Interface

The ABus interface provides the high performance synchronous Data and Control interface to the Host System and/or local memory. Data and Descriptors are transferred via this interface over the 32-bit Data bus (with byte parity). Both multiplexed and non-multiplexed address information is available on this bus. Arbitration and transfer control signals are provided and minimize the requirements for external glue logic.

3.1.3 Control Bus Interface

The Control Interface implements the interface to the Control Bus which allows the user to initialize, monitor and diagnose the operation of the MACSI. The Control Interface is an 8-bit interface. This reduces the pinout and minimizes board space. All information that must be synchronized with the data stream crosses the ABus Interface.

The Control Bus is separated completely from the high performance data path in order to allow independent operation of the processor on the Control Bus. The Control Interface provides synchronization between the asynchronous Control Bus and the synchronous operation of the device.

During operation, the host uses the Control Bus to access the device's internal registers, and to manage the attention/notify (interrupt) logic.

3.2 RING ENGINE

The Ring Engine consists of four blocks: Receiver, Transmitter, MAC Parameter RAM, and Counters/Timers as shown in Figure 3-2.

3.2.1 Receiver

The Receiver accepts data from the PHY level device in byte stream format (PH_Indicate).

Upon receiving the data, the Receiver performs the following functions:

- Determines the beginning and ending of a Protocol Data Unit (PDU)
- Decodes the Frame Control field to determine the PDU type (frame or token)
- Compares the received Destination and Source Addresses with the internal addresses
- Processes data within the frame
- Calculates and checks the Frame Check Sequence at the end of the frame
- Checks the Frame Status field

And finally, the Receiver presents the data to the MAC Interface along with the appropriate control signals (MA_Indicate).

3.2.2 Transmitter

The Transmitter inserts frames from this station into the ring in accordance with the FDDI Timed-Token MAC protocol. It also repeats frames from other stations in the ring. The Transmitter block multiplexes data from the MA_Request Interface and data from the Receiver Block. During frame transmission, data from the Request Interface is selected. During frame repeating, data from the Receiver is selected.

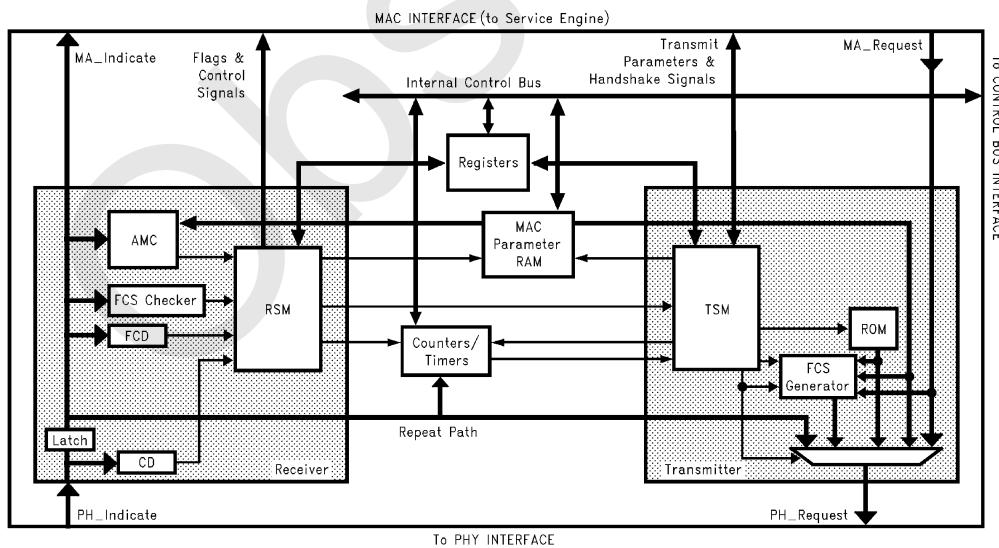

FIGURE 3-2. Ring Engine Block Diagram

TL/F/11705-3

3.0 Architectural Description (Continued)

During frame transmission, the Transmitter performs the following functions:

- Captures a token to gain the right to transmit
- Transmits one or more frames
- Generates the Frame Check Sequence and appends it at the end of the frame
- Generates the Frame Status field that is transmitted at the end of the frame
- Issues the token at the end of frame transmission

During frame repeating, the Transmitter performs the following functions:

- Repeats the received frame and modifies the Frame Status field at the end of the frame as specified by the standard

Whether transmitting or repeating frames, the Transmitter also performs the following functions:

- Strips the frame(s) that are transmitted by this station
- Generates Idle symbols between frames

Data is presented from the Transmitter to the PLAYER+ device in byte stream format (PH_Request).

3.2.3 MAC Parameter RAM

The MAC Parameter RAM is a dual port RAM that contains MAC parameters such as the station's short and long addresses. These parameters are initialized via the Control Interface. Both the Receiver and Transmitter Blocks access the RAM.

The Receiver uses these parameters to compare addresses in incoming frames with the individual and group addresses stored in the Parameter RAM.

The Transmitter uses the Parameter RAM for generating the Source Address for all frames (except when Source Address Transparency is enabled) and for the Destination Address and Information fields on Claim and Beacon frames.

3.2.4 Counters/Timers

The Counter/Timer Block maintains all of the counters and timers required by the ANSI X3T9.5 MAC standard.

Events which occur too rapidly for software to count, such as the various Frame Counts, are included in the Event Counters. The size of the wrap around counters has been chosen to require minimal software intervention even under marginal operating conditions. Most of the counters increment in response to events detected by the Receiver. The counters are readable via the Control Interface.

The Token Rotation and Token Holding Timers which are used to implement the Timed Token Protocol are contained within the Timer Block.

3.3 DATA STRUCTURES

3.3.1 Data Types

The architecture of the MACSI device defines two basic types of objects: Data Units and Descriptors. A Data Unit is a group of contiguous bytes which forms all or part of a frame. A Descriptor is a two-word (64-bit) control object that provides addressing information and control/status information about MACSI device operations.

Data and Descriptor objects may consist of one or more parts, where each part is contiguous and wholly contained within a memory page. Descriptor pages are selectable as all 1 kBytes or all 4 kBytes. Data Units are described by Descriptors with a pointer and a count. A single Data Unit may not cross a 4k boundary. All Descriptors may be marked as **First**, **Middle**, **Last**, or **Only**. Thus, multiple Descriptors may be combined to describe a single entity (i.e. one frame). A single-part object consists of one **Only** Part; a multiple-part object consists of one **First** Part, zero or more **Middle** Parts, and one **Last** Part. In Descriptor names, the object part is denoted in a suffix, preceded by a dot. Thus an Input Data Unit Descriptor (IDUD), which describes the last Data Unit of a frame received from the ring, is called an IDUD.Last.

A Data Unit is stored in contiguous locations within a single 4 kByte page in memory. Multiple-part Data Units are stored in separate, and not necessarily contiguous 4 kByte pages. Descriptors are stored in contiguous locations in Queues and Lists, where each Queue occupies a single 1 kByte or 4 kByte memory page, aligned on the queue-size boundary. For Queues, an access to the next location after the end of a page will automatically wrap-around and access the first location in the page.

Data Units are transferred between the MACSI's Service Engine and Ring Engine via five simplex Channels, three used for Indicate (receive) data and two for Request (transmit) data. Parts of frames received from the ring and copied to memory are called Input Data Units (IDUs); parts of frames read from memory to be transmitted to the ring are called Output Data Units (ODUs).

Descriptors are transferred between the MACSI device and Host via the ABus, whose operation is for the most part transparent to the user. There are five Descriptor types recognized by the MACSI device: Input Data Unit Descriptors (IDUDs), Output Data Unit Descriptors (ODUDs), Pool Space Descriptors (PSPs), Request Descriptors (REQs), and Confirmation Message Descriptors (CNFs).

Input and Output Data Unit Descriptors describe a single Data Unit part, i.e., its address (page number and offset), its size in bytes, and its part (Only, First, Middle, or Last). Frames consisting of a single part are described by a Descriptor.Only; frames consisting of multiple parts are described by a single Descriptor.First, zero or more Descriptor.Middles, and a single Descriptor.Last.

Every Output Data Unit part is described by an ODUD. Output Data Unit Descriptors are fetched from memory so that frame parts can be assembled for transmission.

Every Input Data Unit part is described by an Input Data Unit Descriptor (IDUD). Input Data Unit Descriptors are generated on Indicate Channels to describe where the MACSI device wrote each frame part and to report status for the frame.

Request Descriptors (REQs) are written by the user to specify the operational parameters for the MACSI device Request operations. Request Descriptors also contain the start address of part of a stream of ODUDs and the number of frames represented by the ODUD stream part (i.e., the number of ODUD.Last descriptors). Typically, the user will define a single Request Object consisting of multiple frames of the same request and service class, frame control, and expected status.

3.0 Architectural Description (Continued)

Confirmation Messages (CNFs) are created by the MACSI device to record the result of a Request operation.

Pool Space Descriptors (PSPs) describe the location and size of a region of memory space available for writing Input Data Units.

Request (transmit) and Indicate (receive) data structures are summarized in *Figure 3-3*.

3.3.2 Descriptor Queues and Lists

The MACSI device uses 10 Queues and two Lists which are circular. There are six Queues for Indicate operations, and four Queues and two Lists for Request operations. Each of the three Indicate Channels has a Data Queue containing Pool Space Descriptors (PSPs), and a Status Queue containing Input Data Unit Descriptors (IDUDs). Each Request Channel has a Data Queue containing Request Descriptors (REQs), a Status Queue containing Confirmation Messages (CNFs), and a List containing Output Data Unit Descriptors (ODUDs).

During Indicate and Request operations, Descriptor Queues and Lists are read and written by the MACSI device, using registers in the Pointer and Limit RAM Register files. The Pointer RAM Queue and List Pointer Registers point to a location from which a Descriptor will be read (PSPs and REQs) or written (IDUDs and CNFs). All of the Queues and Lists are strictly unidirectional. The MACSI consumes objects in those queues which are produced by the Host. The Host consumes objects in those queues which are produced by the MACSI.

For each Queue Pointer Register there is a corresponding Queue Limit Register in the Limit RAM Register file, which holds the Queue's limit as an offset value in units of 1 Descriptor (8 bytes). The address in the Queue Pointer is incremented before a Descriptor is read and after a Descriptor is written, then compared with the value in the corresponding Queue Limit Register. When a Queue Pointer Register becomes equal to the Queue Limit Register, an attention is generated, informing the host that the Queue is empty. When a pointer value is incremented past the end of the page, it wraps to the beginning of the page.

3.3.3 Storage Allocation

The maximum unit of contiguous storage allocation in external memory is a Page. All MACSI device addresses consist of a 16-bit page number and a 12-bit offset.

The MACSI device uses a page size of 1 kByte or 4 kBytes for storage of Descriptor Queues and Lists (as selected by the user), and a page size of 4 kBytes for storage of Data Units. A single page may contain multiple Data Units, and multiple-part Data Units may span multiple, disjoint or contiguous pages.

3.4 SERVICE ENGINE

The Service Engine, which manages the operation of the MACSI, contains seven basic blocks: Indicate Machine, Request Machine, Status/Space State Machine, Pointer RAM, Limit RAM, and Bus Interface Unit. An internal block diagram of the Service Engine is shown in *Figure 3-4*.

3.4.1 Indicate Machine

The Indicate Block accepts Service Data Units (frames) from the Ring Engine (MAC) in a byte stream format (MA_Indicate).

3.0 Architectural Description (Continued)

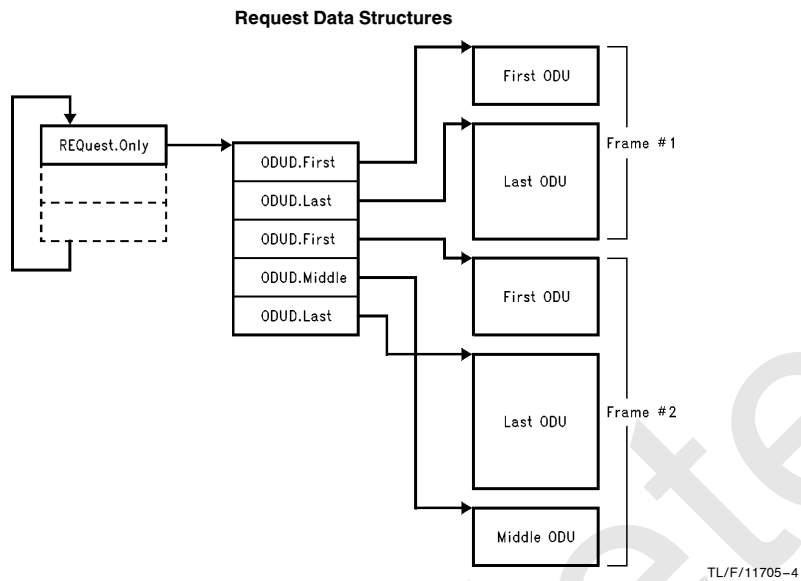

FIGURE 3-3. MACSI Device Data Structures

3.0 Architectural Description (Continued)

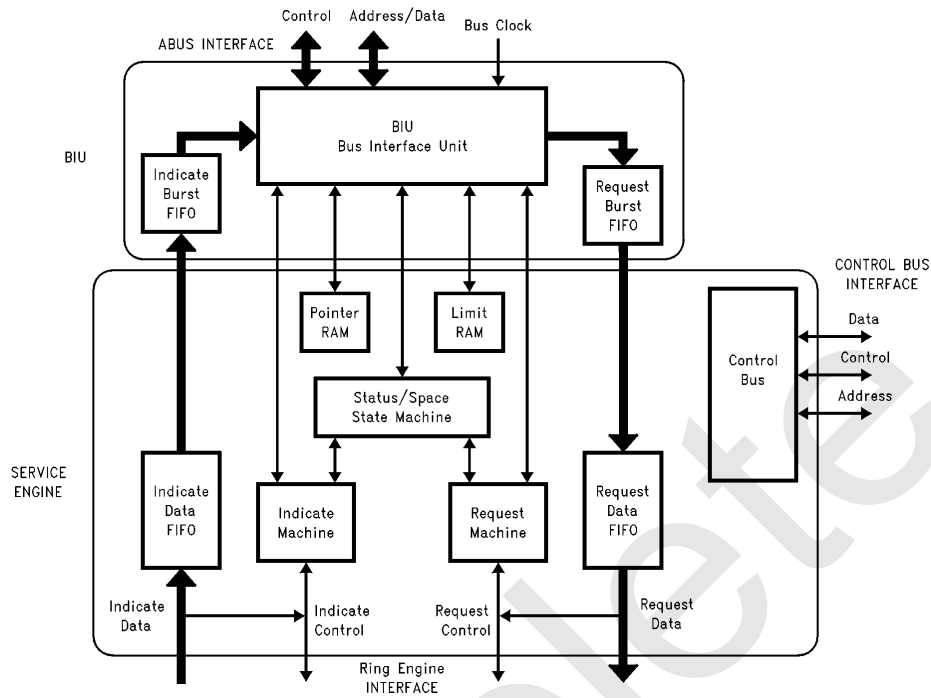

FIGURE 3-4. Service Engine/BIU Internal Block Diagram

TL/F/11705-6

Upon receiving the data, the Indicate Block performs the following functions:

- Decodes the Frame Control field to determine frame type
- Sorts received frames onto Channels according to the Sort Mode
- Optionally Filters identical MAC frames
- Filters Void frames
- Copies the received frames to memory according to Copy Criteria
- Writes status for the received frames to the Indicate Status Queue
- Issues interrupts to the host at host-defined status break-points

3.4.2 Request Machine

The Request Machine presents frames to the Ring Engine (MAC) in a byte stream format (MA_Request).

The Request Machine performs the following functions:

- Reads frames from host memory and assembles them onto Request Channels
- Prioritizes active requests
- Transmits frames to the Ring Engine (MAC)
- Optionally writes status for transmitted and returning frames
- Issues interrupts to the host on user-defined group boundaries

3.4.3 Status/Space Machine

The Status/Space Machine is used by both the Indicate Machine and the Request Machine.

The Status/Space Machine manages all descriptor Queues and writes status for received and transmitted frames.

3.4.4 Bus Interface Unit

The Bus Interface Unit (BIU) is used by both the Indicate and Request Blocks. It manages the ABus Interface, providing the MACSI device with a 32-bit data path to local or system memory.

The Bus Interface Unit controls the transfer of Data Units and Descriptors between the MACSI device and Host memory via the ABus.

Data and Descriptors are transferred between the MACSI device and Host memory. Each Channel type handles a set of Data and Descriptor objects. The three Indicate (Receive) Channels use the following objects:

1. Input Data Units (written by MACSI)
2. Input Data Unit Descriptors (written by MACSI)
3. Pool Space Descriptors (read by MACSI)

The two Request (Transmit) Channels each use the following objects:

1. Output Data Units (read by MACSI)
2. Output Data Unit Descriptors (read by MACSI)
3. Confirmation Message Descriptors (written by MACSI)
4. Request Descriptors (read by MACSI)

3.0 Architectural Description

(Continued)

Each Channel will only process one object type at a time. The BIU arbitrates between the Channels and issues a Bus Request when any Channel requests service. The priority of Channel bus requests is as follows, from highest priority to lowest priority:

1. Indicate Data Unit writes (highest priority when not transmitting)
2. Output Data Unit fetches (highest priority when transmitting)
3. Request Descriptor and Output Data Unit Descriptor fetches
4. Input Data Unit Descriptor writes
5. Confirmation Message Descriptor writes
6. Next Pool Space Descriptor transfer to Current Pool Space Descriptor (internal operation)
7. Pool Space Descriptor fetches
8. Limit RAM Operations (internal operation)
9. Pointer RAM Operations (lowest priority)

Addresses for Channel accesses are contained in the Pointer RAM Registers.

3.4.5 Pointer RAM

The Pointer RAM Block is used by both the Indicate and Request Machines. It contains pointers to all Data Units and Descriptors manipulated by the MACSI device, namely, Input and Output Data Units, Input and Output Data Unit Descriptors, Request Descriptors, Confirmation Message Descriptors, and Pool Space Descriptors.

The Pointer RAM Block is accessed by clearing the PTOp (Pointer RAM Operation) bit in the Service Attention Register, which causes the transfer of data between the Pointer RAM Register and a mailbox location in memory.

3.4.6 Limit RAM

The Limit RAM Block is used by both the Indicate and Request Machines. It contains data values that define the limits of the ten Queues maintained by the MACSI device.

Limit RAM Registers are accessed by clearing the LMOP (Limit RAM Operation) bit in the Service Attention Register, which causes the transfer of data between the Limit RAM Register and the Limit Data and Limit Address Registers.

4.0 FDDI MAC Facilities

4.1 SYMBOL SET

The Ring Engine (MAC) recognizes and generates a set of symbols. These symbols are used to convey Line States (such as the Idle Line State), Control Sequences (such as the Starting and Ending Delimiters) and Data.

Additional information regarding the symbol set can be found in the ANSI X3T9.5 PHY standard.

The Ring Engine expects that the Starting Delimiter will always be conveyed on an even symbol pair boundary (i.e., the JK symbol will always arrive as a byte, not split across two bytes). Following the starting delimiter, data symbols should always come in matched pairs. Similarly the Ending Delimiter should always come in one or more matched symbol pairs.

The symbol pairs conveyed at the PHY Interface are shown in Table 4-1.

4.2 PROTOCOL DATA UNITS

The Ring Engine recognizes and generates Tokens and Frames.

The Token is used to control access to the ring. Only the station that has captured the token has the right to transmit new information. The format of a token is shown in Figure 4-1.

TABLE 4-1. Symbol Pair Set

Type	Symbols
Starting Delimiter	JK or IL
Ending Delimiter	TT or TR or TS or TI
Frame Status	RR or RS or SR or SS
Idle	ll or nl
Data Pair	nn

n represents any data symbol (0-F).

Symbol pairs other than the defined symbols are treated as code violations. Additional information on the symbol pairs generated and interpreted by the Ring Engine can be found in Section 8.2.1.

TABLE 4-2. Frame Fields

Name	Description	Size
SFS	Start of Frame Sequence	
PA	Preamble	8 or more Idle symbol pairs
SD	Starting Delimiter	JK symbol pair
FC	Frame Control Field	1 data symbol pair
DA	Destination Address	2 or 6 symbol pairs
SA	Source Address	2 or 6 symbol pairs
INFO	Information Field	
FCS	Frame Check Sequence	4 symbol pairs
EFS	End of Frame Sequence	
ED	Ending Delimiter	at least 1 T symbol for Frames; at least 2 T symbols for Tokens
FS	Frame Status	3 or more R or S symbols

SFS			EFS
PA	SD	FC	ED

FIGURE 4-1. Token Format

Frames are used to pass information between stations. The format of a frame is shown in Figure 4-2, with the field definitions in Table 4-2.

SFS		Protected by FCS				EFS	
PA	SD	FC	DA	SA	INFO	FCS	ED
							FS

FIGURE 4-2. Frame Format

4.0 FDDI MAC Facilities (Continued)

4.2.1 Frame Fields

Start of Frame Sequence (SFS)

The Start of Frame Sequence consists of the Preamble (PA) followed by the Starting Delimiter (SD).

The Preamble is a sequence of zero or more Idle symbols that is used to separate frames. The Ring Engine Receiver can process and repeat a frame or token with no preamble. The Ring Engine Transmitter generates frames with at least 8 bytes of preamble. The Ring Engine Transmitter also guarantees that valid FDDI frames will never be transmitted with more than 40 bytes of preamble.

The Starting Delimiter is used to indicate the start of a new frame. The Starting Delimiter is the JK Symbol pair.

The Ring Engine expects the Starting Delimiter to be conveyed across the PH_Indication Interface as a single byte. Similarly, the Ring Engine only generates Starting Delimiters aligned to the byte boundary.

Frame Control (FC)

The Frame Control field is used to discriminate frames. For tokens, the FC field identifies Restricted and Non-restricted tokens. For other frames, the FC field identifies the frame type and format and how the frame is to be processed.

The one byte FC field is formatted as shown in *Figure 4-3*.

FIGURE 4-3. Frame Control Field

The C (Class) bit specifies the MAC Service Class as Asynchronous (C = 0) or Synchronous (C = 1).

The L (Length) bit specifies the length of the MAC Address as Short (L = 0) or Long (L = 1). A Short Address is a 16-bit address. A Long Address is a 48-bit address.

The FF (Format) bits specify the frame types as shown in Table 4-3.

The r (Reserved) bit is currently not specified and should always be transmitted as Zero.

The ZZZ (Control) bits are used in conjunction with the C and FF bits to specify the type of frames. These bits may be used to affect protocol processing criteria such as the Priority, Protocol Class, Status Handling, etc.

TABLE 4-3. Frame Control Format Bits

FC.FF		Frame Types
0	0	SMT/MAC
0	1	LLC
1	0	reserved for implementer
1	1	reserved for future standardization

When the Frame Control Format bits (FC.FF) indicate an SMT or MAC frame, the frame type is identified as shown in Table 4-4.

TABLE 4-4. MAC/SMT Frame Types

CLFF	rZZZ	Frame Type
1000	0000	Non-restricted Token
1100	0000	Restricted Token
0L00	0000	Void Frame
0L00	0001 to 1110	SMT Frame
0L00	1111	SMT Next Station Addressing Frame
1L00	0001	Other MAC Frame
1L00	0010	MAC Beacon Frame
1L00	0011	MAC Claim Frame
1L00	0100	MAC Purge Frame
1L00	0101 to 1111	Other MAC Frame

Destination Address (DA)

The Destination Address (DA) field is used to specify the station(s) that should receive and process the frame.

The DA can be an Individual or Group address. This is determined by the Most Significant Bit of the DA (DA.IG). When DA.IG is 0 the DA is an Individual Address, when DA.IG is 1 the DA is a Group Address. The Broadcast/Universal address is a Group Address.

The DA field can be a Long or Short Address. This is determined by the L bit in the FC field (FC.L). If FC.L is 1, the DA is a 48-bit Long Address. If FC.L is 0, the DA is a 16-bit Short Address.

The Ring Engine maintains a 16-bit Individual Address (My Short Address (MSA)), and a 48-bit Individual Address (My Long Address (MLA)).

On the receive side, if DA.IG is 0 the incoming DA is compared with MLA (if FC.L = 1) or MSA (if FC.L = 0). If the received DA matches MLA or MSA the frame is intended for this station and the address recognized flag (A_Flag) is set. If DA.IG is 1, the DA is a Group Address and is compared with the set of Group Addresses recognized by the Ring Engine. If a match occurs the address recognized flag (A_Flag) is set. The A_Flag is used by system interface logic as part of the criteria (with FC.L, DA.IG and M_Flag) to determine whether or not to copy the frame. If the A_Flag is set, the system interface will normally attempt to copy the frame.

On the transmit side, the DA is provided by the system interface logic as part of the data stream. The length of the address to be transmitted is determined by the L bit of the FC field. (The FC field is also passed in the data stream.) The Destination Address can be an Individual, Group, or Broadcast Address.

Source Address (SA)

The Source Address (SA) field is used to specify the address of the station that originally transmitted the frame.

The Source Address has the same length as the Destination Address (i.e., if the DA is a 16-bit Address, the SA is a 16-bit Address; if the DA is a 48-bit Address, the SA is a 48-bit Address).

4.0 FDDI MAC Facilities (Continued)

On the receive side, the incoming SA is compared with either MSA or MLA. If a match occurs between the incoming SA and this station's MLA or MSA, the MFlag is set. This flag is used to indicate that the frame is recognized as having been transmitted by this station and is stripped. The most significant bit of the SA (SA.IG) is not evaluated in the comparison.

On the transmit side, the station's individual address is transmitted as the SA. Since the SA field is normally used for stripping frames from the ring, the SA stored by the Ring Engine normally replaces the SA from the data stream. The length of the address to be transmitted is determined by the L bit of the FC field. (The FC field is passed in the data stream.) The most significant bit of the SA (SA.IG) is normally transmitted as 0, independent of the value passed through the data stream.

As a transmission option, the SA may also be transmitted transparently from the data stream. When the SA Transparency option is used, an alternate stripping mechanism is necessary to remove these frames from the ring. (The Ring Engine provides a Void Stripping Option; see Request Channel 0 and 1 Configuration Registers 0 (R0CR0 and R1CR0) for further information.)

As a separate and independent transmission option, the MSB of the SA may also be transmitted transparently from the data stream. This is useful for end stations participating in the Source Routing protocol that would like to continue to perform reliable stripping based on the SA. (When this option is used without SAT, the transmitted SA is generated by the Ring Engine, as always.)

Information (INFO)

The Information field contains the data transferred between peer users of the MAC data service (SMT, LLC, etc.). There is no INFO field in a Token.

The INFO field contains zero or more bytes.

On the receive side, the INFO field is checked to ensure that it has at least the minimum length for the frame type and contains an even number of symbols, as required by the ANSI X3T9.5 MAC standard.

The first 4 bytes of the INFO field of MAC frames are stored in an internal register and compared against the INFO field of the next MAC frame. If the data of the two frames match and both frames were MAC frames, the SameInfo signal is generated. This signal may be used to copy MAC frames only when new information is present.

On the transmit side, the Ring Engine does not limit the maximum size of the INFO field, but it does insure that frames are transmitted with a valid DA and SA.

Frame Check Sequence (FCS)

The Frame Check Sequence is a 32-bit Cyclic Redundancy Check that is used to check for data corruption in frames. There is no FCS field in a Token.

On the receive side, the Ring Engine checks the FCS to determine whether the frame is valid or corrupted.

On the transmit side, the FCS field is appended to the end of the INFO field. As a transmission option, appending the FCS to the frame can be inhibited (FCS Transparency).

End of Frame Sequence (EFS)

The End of Frame Sequence (EFS) always begins with a T symbol and should always contain an even number of symbols. For Tokens, an additional T symbol is added. For frames, the Ending Delimiter (ED) is followed by one or more of Frame Status Indicators (FS).

The Frame Status (FS) field is used to indicate the status of the frame. The FS field consists of three Indicators: Error Detected (E), Address Recognized (A), and Frame Copied (C). These Indicators are created and modified as specified in the ANSI X3T9.5 MAC standard.

For frames transmitted by the Ring Engine, the E, A and C Indicators are appended to all frames and are transmitted as R symbols. No provisions are made to generate additional trailing control indicators.

For frames repeated by the Ring Engine, the E, A and C Indicators are handled as specified in the Standard. Additional trailing control indicators are repeated unmodified provided they are properly aligned. See Section 5.5 for details on Frame Status Processing.

4.2.2 Token Formats

The Ring Engine supports non-restricted and restricted Tokens. See Figure 4-4 and Figure 4-5.

SFS	FC	EFS
SD	80	ED

FIGURE 4-4. Non-Restricted Token Format

SFS	FC	ED
SD	C0	ED

FIGURE 4-5. Restricted Token Format

Non-restricted

A non-restricted token is used for synchronous and non-restricted asynchronous transmissions. Each time the non-restricted token arrives, a station is permitted to transmit one or more frames in accordance with its synchronous bandwidth allocation regardless of the status of the token (late or early).

Asynchronous transmissions occur only if the token is early (usable token) and the Token Holding Timer has not reached the selected threshold.

Restricted

A restricted token is used for synchronous and restricted asynchronous transmissions only.

A station which initiates the restricted dialogue captures a non-restricted token and releases a restricted token. Stations that participate in the restricted dialogue are allowed to capture the restricted token. A station ends the restricted dialogue by capturing the restricted token and releasing a non-restricted token.

4.2.3 Frame Formats

The Ring Engine supports all of the frame formats permitted by the FDDI standard. All frame types may be created external to the Ring Engine and be passed through the MAC Request Interface to the Ring. The Ring Engine also has the ability to generate Void, Beacon, and Claim frames internally.

4.0 FDDI MAC Facilities (Continued)

Frames Generated Externally

The Ring Engine transmits frames passed to it from the System Interface. The data portion of the frame is created by the System Interface. The data portion begins with the FC field and ends with the last byte of the INFO field. The FC field is passed transparently to the ring. The length bit in the FC field is used to determine the length of the transmitted addresses. The data is passed as a byte stream across the MAC Request Interface as shown in Table 4-5.

TABLE 4-5. Frame Formats

Field	Size (bytes)	MA_Request	PH_Request
PA	≥8; ≤40		Idle Pairs
SD	1		JK
FC	1	FC	FC
DA	2 or 6	DA	DA
SA	2 or 6	SA	MSA, MLA, or SA
INFO	≥0	INFO	INFO
FCS	4 if present	FCS	FCS
ED	1		TR
FS	1		RR

Before the frame is transmitted, the Ring Engine inserts the Start of Frame Sequence with at least 8 bytes of Preamble but no more than 40 bytes of Preamble. The starting delimiter is transmitted as a JK symbol pair. The Source Address is normally transmitted by the Ring Engine since it uses the Source Address to determine when to strip a frame from the ring. This can be overridden by using the Source Address transparency capability. Similarly, the Frame Check Sequence (4 bytes) is normally transmitted by the Ring Engine. This can be overridden with the FCS transparency capability. With FCS transparency, the FCS is transmitted from the data stream. The End of Frame Sequence is always transmitted by the Ring Engine as TR RR.

Frames Generated by Ring Engine

The Ring Engine generates and detects several frames in order to attain and maintain an operational ring.

Void Frames

Void frames are used during normal operation. The Ring Engine generates two types of void frames: regular Void frames and My_Void frames.

If Short addressing is enabled, Void frames with the short address (MSA) are transmitted. Otherwise, Void frames with the long address (MLA) are transmitted. Table 4-6 shows the Void frame format.

Void frames are transmitted in order to reset the Valid Transmission timers (TVX) in other stations to eliminate unnecessary entry to the Claim state. Stations are not required to copy Void frames. Void frames are transmitted by the Ring Engine in two situations:

1. While holding a token when no data is ready to be transmitted.
2. After a frame transmission is aborted.

My_Void frames are transmitted by the Ring Engine in three situations:

1. After a request to measure the Ring Latency has been made and the next early token is captured.
2. After this station wins the Claim process and before the token is issued.
3. After a frame has been transmitted with the STRIP option and before the token for that service opportunity is issued.

Void frames are also detected by the Ring Engine. A Void frame with a Source Address other than MSA or MLA is considered an Other_Void frame.

Claim Frames

Claim frames are generated continuously with minimum preamble while the Ring Engine is in the Transmit Claim state.

The format of Claim frames generated by the Ring Engine is shown in Table 4-7. When long addressing is enabled, frames with the long address (MLA) are transmitted. Otherwise frames with the short address (MSA) are transmitted.

The Ring Engine detects reception of valid Claim frames. A comparison is performed between the first four bytes of the received INFO field and the value of TREQ programmed in the parameter RAM in order to distinguish Higher_Claim, Lower_Claim, Duplicate_Claim, and My_Claim.

Beacon Frames

Beacon frames are transmitted continuously with minimum preamble when the Ring Engine is in the Transmit Beacon state. The format of Beacon frames generated by the Ring Engine is shown in Table 4-8. When long addressing is enabled, frames with the long address (MLA) are transmitted. Otherwise frames with the short address (MSA) are transmitted.

4.0 FDDI MAC Facilities (Continued)

TABLE 4-6. Void Frames

Type	Enable	Size	SFS		FC	DA	SA	FCS	EFS
Void	ESA	Short	PA	SD	00	null	MSA	FCS	TRRR
Void	not ESA	Long	PA	SD	40	null	MLA	FCS	TRRR
My__Void	ESA	Short	PA	SD	00	MSA	MSA	FCS	TRRR
My__Void	not ESA	Long	PA	SD	40	MLA	MLA	FCS	TRRR

TABLE 4-7. Claim Frames

Type	Enable	Size	SFS		FC	DA	SA	INFO	FCS	EFS
My__Claim	not ELA	Short	PA	SD	83	MSA	MSA	TREQ	FCS	TRRR
My__Claim	ELA	Long	PA	SD	C3	MLA	MLA	TREQ	FCS	TRRR

TABLE 4-8. Beacon Frames

Type	Enable	Size	SFS		FC	DA	SA	INFO	FCS	EFS
My__Beacon	not ELA	Short	PA	SD	82	null	MSA	TBT	FCS	TRRR
My__Beacon	ELA	Long	PA	SD	C2	null	MLA	TBT	FCS	TRRR

When the Transmit Beacon State is entered from the Transmit Claim State the first byte of the 4 byte TBT field is transmitted as Zero.

Beacon frames that require alternative formats such as Directed Beacons must be generated externally.

The Ring Engine detects reception of valid Beacon frames and distinguishes between Beacon frames transmitted by this MAC (My__Beacon) and Beacon frames transmitted by other stations (Other__Beacon).

4.3 FRAME COUNTS

To aid in fault isolation and to enhance the management capabilities of a ring, the Ring Engine maintains several frame counts. The Error and Isolated frame counts increment when a frame is received with one or more errors that were previously undetected. The Ring Engine then modifies the Error Control Indicator so that a downstream station will not increment its count.

The size of the counters has been chosen such that minimal software intervention is required, even under marginal operating conditions.

The following counts are maintained by the Ring Engine:

FRCT Frame Received
 EICT Error Isolated
 LFCT Lost Frame
 FCCT Frames Copied with Ax set
 FNCT Frames Not Copied with Ax set
 FTCT Frames Transmitted

4.3.1 Frame Received Count (FRCT)

The Frame Received Count is described in the FDDI MAC standard, and is the count of all complete frames received. This count includes frames stripped by this station.

4.3.2 Error Isolated Count (EICT)

The Error Isolated Count is described in the FDDI MAC standard, and is the count of error frames detected by this station and no previous station. It increments when:

1. An FCS error is detected and the received Error Indicator (Er) is not equal to S.
2. A frame of invalid length (i.e., off boundary T) is received and Er is not equal to S.
3. Er is not R or S.

4.3.3 Lost Frame Count (LFCT)

The Lost Frame Count is described in the FDDI MAC standard, and is the count of all instances where a format error is detected in a frame or token such that the credibility of reception is placed in doubt. The Lost Frame Count is incremented when any symbol other than data or Idle symbols is received between the Starting and Ending Delimiters of a frame (this includes parity errors).

4.3.4 Frame Copied Count (FCCT)

The Frame Copied Count is described in the FDDI MAC standard, and is the count of the number of frames addressed to and copied by this station. The count is incremented when an internal or external match occurs (when Option.EMIND enabled) on the Destination Address, no errors were detected in the frame and the frame was successfully copied (which the Service Engine communicates to the Ring Engine via the internal VCOPY signal). Frames copied promiscuously, MAC frames, Void frames and NSA frames received with the A indicator set are not included in this count.

4.0 FDDI MAC Facilities (Continued)

4.3.5 Frames Not Copied Count (FNCT)

The Frames Not Copied Count is specified in the FDDI MAC standard, and is the count of frames intended for this station that were not successfully copied by this station. The count is incremented when an internal or external (when Option.EMIND is enabled) Destination Address match occurs, no errors were detected in the frame, and the frame was not successfully copied (VCOPY = 0). MAC frames, Void frames, and NSA frames received with the A indicator set are not included in this count.

4.3.6 Frames Transmitted Count (FTCT)

The Frames Transmitted Count is specified in the FDDI MAC standard, and is incremented every time a complete frame is transmitted from the MAC Request Interface. Void and MAC frames generated by the Ring Engine are not included in the count.

4.4 TIMERS

4.4.1 Token Rotation Timer (TRT)

The Token Rotation Timer (TRT) times token rotations from arrival to arrival. TRT is used to control ring scheduling during normal operation and to detect and recover from serious ring error situations.

TRT is loaded with the maximum token rotation time, TMAX, when the ring is not operational. TRT is loaded with the negotiated Target Token Rotation Time, TNEG, when the ring is operational.

4.4.2 Token Holding Timer (THT)

The Token Holding Timer is used to limit the amount of ring bandwidth used by a station for asynchronous traffic once the token is captured. THT is used to determine if the captured token is (still) usable for asynchronous transmission. A token is usable for asynchronous traffic if THT has not reached the selected threshold. Two asynchronous thresholds are supported; one that is fixed at the Negotiated Target Token Rotation Time (TNEG), and one that is programmable at one of 16 Asynchronous Priority Thresholds. Requests to transmit frames at one of the priority thresholds are serviced when the Token Holding Timer (THT) has not reached the selected threshold.

4.4.3 Late Count (LTCT)

The Late Count is implemented differently than suggested by the MAC standard, but provides similar information. The function of the Late Count is divided between the Late__Flag that is equivalent to the MAC standard Late Count with a non-zero value and a separate counter. Late__Flag is maintained by the Ring Engine to indicate if it is possible to send asynchronous traffic. When the ring is operational, Late Count indicates the time it took the ring to recover the last time the ring became non-operational. When the ring is non-operational, Late Count indicates the time it has taken (so far) to recover the ring.

The Late Count is incremented every time TRT expires while the ring is non-operational and Late__Flag is set (once every TMAX).

The Late Count is provided to assist Station Management, SMT, in the isolation of serious ring errors. In many situations the ring will recover very quickly and late count will be of marginal utility. However, in the case of serious ring er-

rors, it is helpful for SMT to know how long it has been since the ring became non-operational (with TMAX resolution) in order to determine if it is necessary to invoke recovery procedures. When the ring becomes non-operational, there is no way to know how long it will stay non-operational. Therefore, a timer is necessary. If the Late Count were not provided, SMT would be forced to start a timer every time the ring becomes non-operational even though it may seldom be used. By using the provided Late Count, an SMT implementation may be able to alleviate this additional overhead.

4.4.4 Valid Transmission Timer (TVX)

The Valid Transmission Timer (TVX) is reset every time a valid frame or token is received. TVX is used to increase the responsiveness of the ring to errors. Expiration of the TVX indicates that no frame or token has been received within the timeout period and causes the Transmitter to invoke the recovery (Claim) process.

The Value of TVX is also used as the Duplicate MAC frame detection delay, DM__MIN. This is the time after which a MAC frame will be suspected as being generated by another station with this station's address when the ring is non-operational.

4.4.5 Token Received Count (TKCT)

The Token Received Count is incremented every time a valid token arrives. The Token Count can be used with the Ring Latency Count to calculate the average network load over a period of time. The frequency of token arrival is inversely related to the network load.

4.4.6 Ring Latency Count (RLCT)

The Ring Latency Count is a measurement of time for frames to propagate around the ring. This counter contains the last measured ring latency whenever the Ring Latency Valid bit of the Token Event Register (TELRO.RLVLD) is One.

The Latency Counter increments every 16 byte times (1.28 μ s) and is used to measure ring latencies up to 1.3421772 seconds directly with accuracy of 1.2 μ s. No overflow or increment event is provided with this counter.

4.5 RING SCHEDULING

FDDI uses a timed token protocol to schedule use of the ring. The protocol measures load on the network by timing the rotation of the token. The longer the token rotation time the greater the instantaneous load on the network. By limiting the transmission of data when the token rotation time exceeds a target rotation time, a maximum average token rotation time is realized. The protocol is used to provide different classes of service.

Multiple classes of service can be accommodated by setting different target token rotation times for each class of service.

The Ring Engine supports Synchronous, Non-restricted Asynchronous, Restricted Asynchronous, and Immediate service classes. The Immediate service class is supported when the ring is non-operational; the other classes are supported when the ring is operational.

4.5.1 Synchronous Service Class

The Synchronous Service Class may be used to guarantee a maximum response time (2 times TTRT), minimum bandwidth, or both.

4.0 FDDI MAC Facilities (Continued)

Each time the token arrives, a station is permitted to transmit one or more frames in accordance with its synchronous bandwidth allocation regardless of the status of the token (late or early; Restricted or Non-Restricted).

Since the Ring Engine does not provide a mechanism for monitoring a station's synchronous bandwidth utilization, the user must insure that no synchronous request requires more than the allocated bandwidth.

To help ensure that synchronous bandwidth is properly allocated after ring configuration, synchronous requests are not serviced after a Beacon frame is received. After a major reconfiguration has occurred, management software must intervene to verify or modify the current synchronous bandwidth allocation.

4.5.2 Non-Restricted Asynchronous Service Class

The Non-Restricted Asynchronous service class is typically used with interactive and background traffic. Non-Restricted Asynchronous requests are serviced only if the token is early and the Token Holding Timer has not reached the selected threshold.

Asynchronous service is available at two priority thresholds, the Negotiated Target Token Rotation Time plus one programmable threshold. Management software may use the priority thresholds to discriminate additional classes of traffic based on current loading characteristics of the ring. The priority thresholds may be determined using the current TTRT and the Ring Latency. In this case, application software is only concerned with the priority level of a request.

As an option, Asynchronous Requests may be serviced with THT disabled. This is useful when it is necessary to guarantee that a multi-frame request will be serviced on a single token opportunity. Because of the possibility of causing late tokens, this capability should be used with caution, and should only be allowed when absolutely necessary.

4.5.3 Restricted Asynchronous Service Class

The Restricted Asynchronous service class is useful for large transfers requiring all of the available Asynchronous bandwidth. The Restricted Token service is useful for large transfers requiring all of the available (remaining) asynchronous bandwidth.

The Restricted Token service may also be used for operations requiring instantaneous allocation of the remaining synchronous bandwidth when Restricted Requests are serviced with THT disabled. This is useful when it is necessary to guarantee atomicity, i.e., that a multi-frame request will be serviced on a single token opportunity.

A Restricted dialogue consists of three phases:

1. Initiation of a Restricted dialogue:
 - Capture a Non-restricted Token
 - Transmit zero or more frames to establish a Restricted dialogue with other stations
 - Issue a Restricted Token to allow other stations in the dialogue to transmit frames
2. Continuation of a Restricted dialogue:
 - Capture a Restricted Token
 - Transmit zero or more frames to continue the Restricted dialogue
 - Issue a Restricted Token to allow other stations in the dialogue to transmit frames

3. Termination of a Restricted dialogue:

- Capture a Restricted Token
- Transmit zero or more frames to continue the Restricted dialogue
- Issue a Non-Restricted Token to return to the Non-Restricted service class

Initiation of a Restricted dialogue will prevent all Non-Restricted Asynchronous traffic throughout the ring for the duration of the dialogue, but will not affect Synchronous traffic.

To ensure that the Restricted traffic is operating properly, it is possible to monitor the use of Restricted Tokens on the ring. When a Restricted Token is received, the event is latched and, under program control, may generate an interrupt. In addition, a request to begin a Restricted dialogue will only be honored if both the previous transmitted Token and the current received Token were Non-Restricted tokens. This is to ensure that the upper bound on the presence of a Restricted dialogue in the ring is limited to a single dialogue.

As suggested by the MAC-2 standard, to help ensure that only one Restricted dialogue will be in progress at any given time, Restricted Requests are not serviced after a MAC frame is received until Restricted Requests are explicitly enabled by management software. Since the Claim process results in the generation of a Non-restricted Token, this prevents stations from initiating another restricted dialogue without the intervention of management software.

4.5.4 Immediate Service Class

The Immediate Service Class facilitates several non-standard applications and is useful in ring failure recovery (e.g., Transmission of Directed Beacons). Certain ring failures may cause the ring to be unusable for normal traffic, until the failure is remedied.

Immediate requests are only serviced when the ring is non-operational. Immediate requests may be serviced from the Transmitter Data, Claim, and Beacon States. Options are available to force the Ring Engine to enter the Claim or Beacon State, to prohibit it from entering the Claim State, or to remain in the Claim State when receiving My_Claim.

On the completion of an Immediate request, a Token (Non-restricted or Restricted) may optionally be issued. Immediate requests may also be used in non-standard applications such as a full duplex point to point link.

5.0 Functional Description (Ring Engine)

5.1 TOKEN HANDLING

5.1.1 Token Timing Logic

The FDDI Ring operates based on the Timed Token Rotation protocol where all stations on the ring negotiate for the maximum time that the stations have to wait before being able to transmit frames. This value is termed the Negotiated Target Token Rotation Time (TTRT). The TTRT value is stored in the TNEG Register.

Stations negotiate for TTRT based on their TREQ that is assigned to them upon initialization.

Each station keeps track of the token arrival by setting the Token Rotation Timer (TRT) to the TTRT value. If the token

5.0 Functional Description (Continued)

is not received within TTRT (the token is late), the event is recorded by setting the Late_Flag. If the token is not received within twice TTRT (TRT expires and Late_Flag is set), there is a potential problem in the ring and the recovery process is invoked.

Furthermore, the Token Holding Timer (THT) is used to limit the amount of ring bandwidth used by a station for asynchronous traffic once the token is captured. Asynchronous traffic is prioritized based on the Late_Flag which denotes a threshold at TTRT and an additional Asynchronous Priority Threshold (THSH). The Asynchronous Threshold comparison (Apt 1) is pipelined, so a threshold crossing may not be detected immediately; however, the possible error is a fraction of the precision of the threshold values.

The Token Timing Logic consists of two Timers, TRT and THT, in addition to the TMAX and TNEG values loaded into these counters (see *Figure 5-1*).

The Timers are implemented as count-up counters that can increment every 80 ns. The Timers are reset by loading TNEG or TMAX into the counters where TNEG and TMAX are unsigned two's complement numbers. This allows a Carry flag to denote timer expiration.

On an early token arrival (Late_Flag is not set), TRT is loaded with TNEG and counts up. On a late token arrival (Late_Flag is set), Late_Flag is cleared and TRT continues to count. When TRT expires and Late_Flag is not set, Late_Flag is set and TRT is loaded with TNEG.

THT follows the value of TRT until a token is captured. When a token is captured, TRT may be reloaded with TNEG while THT continues to count from its previous value (THT does not wrap around). THT increments when enabled. THT is disabled during synchronous transmission and a special class of asynchronous transmission. THT is used to determine if the token is usable for asynchronous requests. For these purposes, the token is considered late one byte before it is actually late (to promote interoperability with less careful implementations).

If TRT expires while Late_Flag is set, TRT is loaded with TMAX and the recovery process (Claim) is invoked (unless the Inhibit Recovery Required option is set). The Recovery

Required condition becomes true one byte time after TRT expires (to promote interoperability with less careful implementations). When TRT expires and the ring is not operational, TRT is loaded with TMAX. TRT is also loaded with TMAX on a MAC Reset.

5.1.2 Token Recovery

While the ring is operational, every station in the ring uses the Negotiated Target Token Rotation Time, TNEG. The MAC implements the protocol for negotiation of this target token rotation time (TTRT) through the Claim process. The shortest requested token rotation time is used by all of the stations in the ring as the TNEG.

If TRT expires with Late_Flag set, a token has not been received within twice TTRT (Target Token Rotation Time). If TVX (Valid Transmission Timer) expires, the station has not received a valid token within TVX Max. Both these events require token recovery and cause the Ring Engine to enter the Claim process.

In the Claim process, a MAC continuously transmits Claim frames containing TREQ. Should the MAC receive a Claim frame with a shorter TREQ (larger value—Higher_Claim) it leaves the Claim State. A station that receives its own Claim frame gains the right to send the first token and make the ring operational again. If the Claim Process does not complete successfully, TRT will expire and the Beacon Process is invoked.

The Beacon Process is used for fault isolation. A station may invoke the Beacon Process through an SM_Control.request(Beacon). When a station enters the Beacon Process, it continuously sends out Beacon Frames. The Beacon Process is complete when a station receives its own Beacon Frame. That station then enters the Claim process, to re-initialize the ring.

5.2 SERVICING TRANSMISSION REQUESTS

A Request to transmit one or more frames is serviced by the Ring Engine. After a Request is submitted to the Ring Engine, the Ring Engine awaits an appropriate Service Opportunity in which to service the Request. Frames associated with the Request are transmitted during the Service Opportunity. The definition of a Service Opportunity is different depending on the operational state of the ring.

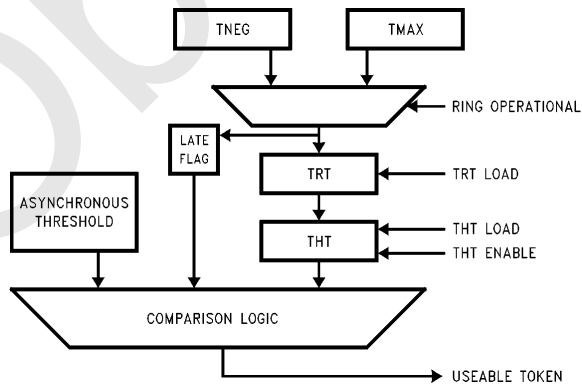

FIGURE 5-1. Token Timing Logic

TL/F/11705-7

5.0 Functional Description (Ring Engine) (Continued)

A Service Opportunity begins when the criteria presented to the Ring Engine are met. This criteria contains the requested service class (sync, async, async priority, immediate) and the type of token to capture (restricted, non-restricted, any, none).

During a service opportunity, the Ring Engine guarantees that a valid frame is sent with at most 40 bytes of preamble (unless Option.IRPT is set). When data is not ready to be transmitted, Void frames are transmitted to reset the TVX timers in all stations. During an immediate request from the Claim or Beacon state, if the data for external Claim or Beacon frame is not ready to be transmitted, the Ring Engine will transmit Claim or Beacon frames using the same internal data used for normal Claim and Beacon processing.

5.2.1 Service Opportunity while Ring Operational

Beginning of Service Opportunity

Table 5-1 shows the conditions that must be true when a valid token is received in order to begin a service opportunity when the ring is operational.

In addition to the criteria mentioned above, additional criteria apply to the servicing of Synchronous and Restricted Requests.

- Synchronous Requests are not serviced if RELR.BCNR = 1 (see Section 4.5.1).
- Restricted requests are not serviced when RELR.MACR = 1. (see Section 4.5.3).
- Restricted Dialogues may only begin when a non-restricted token has been received and transmitted (see Section 4.5.3).

End of Service Opportunity

The Service Opportunity continues until either a token is issued or the ring becomes non-operational.

A token is issued after the current frame, if any, is transmitted when:

1. It is no longer necessary to hold the token
 - All frames of all active requests have been transmitted
2. The token became unusable while servicing a request
 - Asynchronous Priority threshold reached (if an Async Priority Request is being serviced)
 - THT expired (if enabled)

When the ring becomes non-operational the current frame transmission is aborted. The ring may go non-operational while holding a token as a result of any one of the following conditions being present:

- A MAC Reset
- Reception of a valid MAC frame
- TRT expiration (TRT was reset when the token was captured)

Issue Token Type

The criteria presented to the Ring Engine to begin a service opportunity also contains the Issue Token Class. The Issue Token Class is used if servicing of that request was completed (the last frame of that request was transmitted). Otherwise, a token of the capture token class is issued.

TABLE 5-1. Beginning of Service Opportunity

Requested Service Class	Requested Token Capture Class	Criteria	Received Token Class
Asynchronous Priority	non-restricted	THT > THSH Late_Flag = 0 Ring_Op = 1	non-restricted
Asynchronous	non-restricted	Late_Flag = 0 Ring_Op = 1	non-restricted
Asynchronous	restricted	Late_Flag = 0 Ring_Op = 1	restricted
Synchronous	any	Ring_Op = 1	any

When servicing multiple requests on a single service opportunity, the issue token class of the previous class becomes the capture class for the next request for purposes of determining usability.

The type of token issued depends on the service class and the type of token captured as shown in Table 5-2.

5.2.2 Service Opportunity While Ring Not Operational

While the ring is not operational, a service opportunity occurs if an immediate transmission is requested from the transmitter Data, Claim or Beacon state, and the transmitter is in the appropriate state.

The service opportunity continues until any one of the following conditions exist:

1. No (additional) frames are to be sent
2. Time TMAX elapses on this request
3. The transmitter exits the requested state
4. The ring becomes operational while servicing an immediate request

5.2.3 Frame Transmission

Frames associated with the current request may be transmitted at any time during a Service Opportunity. In many applications, data is ready to be transmitted when the Request is presented to the interface. Soon after the Service Opportunity begins, frame transmission begins. In other applications, in order to minimize the effects of ring latency, it is desirable to capture the token when no data is ready to be transmitted. This capability results in wasted ring bandwidth and should be used judiciously.

During transmission, a byte stream is passed from the System Interface to the MAC Request Interface. The data is passed through the Ring Engine and appears at the PHY Request Interface two byte times later.

While a frame is being transmitted, the Request parameters for the next Request (if different) may be presented to the interface. At the end of the current frame transmission, a decision is made to continue or cancel the current service opportunity based on the new Request parameters.

Several errors can occur during a transmission. A transmission may be terminated unsuccessfully because of external buffering or interface parity errors, internal Ring Engine errors, a MAC reset, or reception of a MAC frame. When a

5.0 Functional Description (Ring Engine) (Continued)

transmission is aborted due to an external error (and Option.IRPT is not set), a Void frame is transmitted to reset the TVX timers in all stations in the ring. When a frame is aborted due to a transmission error, the service opportunity is not automatically ended.

5.3 REQUEST SERVICE PARAMETERS

5.3.1 Request Service Class

The Requested Service corresponds to the Request Service Class and the Token Class parameters of the (SM_)MA_DATA.request and (SM_)MA-Token.request primitives as specified in the Standard.

TABLE 5-2. Token Transmission Type

Service Class	Token Captured	Token Issued
Non-restricted	Non-restricted	Non-restricted
Begin Restricted	Non-restricted	Restricted
Continue Restricted	Restricted	Restricted
End Restricted	Restricted	Non-restricted
Immediate	None	None
Immediate Non-restricted	None	Non-restricted
Immediate Restricted	None	Restricted

14 useful combinations of the requested Service Class (Non-Restricted Asynchronous, Restricted Asynchronous, Synchronous, Immediate), the Token Capture and Issue Class, and THT Enable are supported by the Ring Engine as shown in Table 5-3.

Requests are serviced on a Service Opportunity meeting the requested criteria.

A Token Capture Class of **non-rstr** indicates that the Transmitter Token Class must be Non-Restricted to begin servicing the request. A Token Capture Class of **rstr** indicates that the Transmitter Token Class must be Restricted to begin servicing the Request. A Token Issue Class of **non-rstr** means that the Transmitter Token Class will be Non-restricted upon completion of the request. A Token Issue Class of **rstr** means that the Transmitter Token Class will be Restricted upon completion of the request.

5.3.2 Request Options

The Request options provide the ability for Source Address Transparency (SAT) and FCS Transparency (FCST). In both cases, data from the request stream is transmitted in place of data from the Ring Engine. The use of Source Address Transparency has no effect on the sequencing of the interface. When Source Address transparency is not used, the SA from the internal parameter RAM is substituted for the SA bytes in the request stream, which must still be present. Since the FCS is appended to the frame, when FCS transparency is not used, no FCS bytes are present in the request stream.

Source Address Transparency (SAT)

Normally, the SA field in a frame is generated by the Ring Engine using either the MSA or MLA values programmed in the parameter RAM. When the SA Transparency option is selected, the SA from the data stream is transmitted in

place of the MSA or MLA. The SAT option can be invoked on a Request Object via the Request Configuration parameters of the System Interface.

When the SA Transparency option is selected, it is necessary to rely on an alternate stripping mechanism since stripping based on the returning SA only guarantees that frames with MSA or MLA will be stripped. Either the Void Stripping option (described below) may be invoked, or external hardware that forces stripping using the EM (External M_Flag) signal is required.

The MSB of the SA is not controlled by this option. It is normally forced to Zero. It can be controlled using the Source Address MSB Transparency option described below.

SA Transparency is possible for all frames (including MAC frames). External support is required to limit the use of SA Transparency to certain MAC Users. SA Transparency should not be used with externally generated MAC Frames in order to maintain accountability, but this is not enforced by the Ring Engine. When SA Transparency is used with externally generated Beacon Frames that are transmitted from the Beacon state, the first 4 bytes of the INFO field are passed transparently from the data stream instead of being generated by the Ring Engine.

SA Transparency also overrides the Long and Short Addressing enables. For example, if Long Addressing is not enabled, it is still possible to transmit frames with Long Addresses. Similarly, if Short Addressing is not enabled, it is still possible to transmit Frames with Short Addresses. This may be useful in full duplex point to point applications and for diagnostic purposes.

Source Address Most Significant Bit Transparency

With the Source Address MSB Transparency option, the MSB of the SA is sourced from the data stream, as opposed to being transmitted as Zero. The SA MSB Transparency option is selected through the Request Channel Configuration Registers in the Service Engine.

Unless the Source Address Transparency option is also selected, the rest of the SA is generated by the Ring Engine.

The MSB of the SA is used to denote the presence of the Routing Information Field used in Source Routing algorithms (as in the IEEE 802.5 protocol). This option is useful for stations that use Source Routing. In these applications, the SA can still be generated by the Ring Engine, even when routing information is inserted into the data stream. This allows the normal stripping to be accomplished in end stations implementing Source Routing (without relying on external software to not create no-owner frames).

Void Stripping

This option is useful for removing bridged and ownerless frames and remnants (fragments) from the ring.

In the Void Stripping protocol, two My_Void frames are transmitted at the end of a service opportunity. Stripping continues until one of the following conditions occur:

- One My_Void frame returns (The Second My_Void will be stripped on the basis of the SA)
- A Token is received
- An Other_Void is received
- A MAC frame other than My_Claim is received
- A MAC Reset occurs

5.0 Functional Description (Ring Engine) (Continued)

If any frame of a service opportunity requests this option, then all frames on that service opportunity will be stripped using this method. Void Stripping is invoked upon the assertion of the STRIP signal at the beginning of a frame transmission.

Void Stripping is also automatically invoked by this station if it wins the Claim token process before the initial token is issued. This removes all fragments and ownerless frames from the ring when the ring becomes operational.

FCS Transparency

Normally, the Ring Engine generates and transmits the FCS. When the Frame Check Sequence Transparency op-

tion is selected, the Ring Engine device does not append the FCS to the end of the Information field. This option is selected by asserting signal FCST.

The receiving stations treat the last four bytes of the data stream as the FCS.

This option may be useful for end to end FCS coverage when crossing FDDI bridges, for diagnostic purposes, or in Implementer frames.

5.4 FRAME VALIDITY PROCESSING

A valid frame is a frame that meets the minimum length criteria and contains an integral number of data symbol pairs between the Starting and Ending Delimiters as shown in Table 5-4.

Obsolete

5.0 Functional Description (Ring Engine) (Continued)

TABLE 5-3. Request Service Classes

RQRCLS	Name	Class	THT	Token Capture	Token Issue	Notes
0000	None	None				
0001	Apri_1	Async THSH1	enabled	non-rstr	non-rstr	
0010	Reserved	Reserved				
0011	Reserved	Reserved				
0100	Sync	Sync	disabled	any	captured	1
0101	Imm	Immediate	disabled	none	none	4
0110	ImmN	Immediate	disabled	none	non-rstr	4
0111	ImmR	Immediate	disabled	none	rstr	4
1000	Async	Async	enabled	non-rstr	non-rstr	
1001	Rbeg	Restricted	enabled	non-rstr	rstr	2, 3
1010	Rend	Restricted	enabled	rstr	non-rstr	2
1011	Rcnt	Restricted	enabled	rstr	rstr	2
1100	AsynD	Async	disabled	non-rstr	non-rstr	
1101	RbeginD	Restricted	disabled	non-rstr	rstr	2, 3
1110	RendD	Restricted	disabled	rstr	non-rstr	2
1111	RcntD	Restricted	disabled	rstr	rstr	2

Note 1: Synchronous Requests are not serviced when RELR.BCNR = 1.

Note 2: Restricted Requests are not serviced when RELR.MACR = 1.

Note 3: Restricted Dialogues only begin when a Non-Restricted token has been received and transmitted.

Note 4: Immediate Requests are serviced when the ring is Non-Operational. These requests are serviced from the Data state if neither signal RQCLM nor RQBCN is asserted. If signal RQCLM is asserted, Immediate Requests are serviced from the Claim State. If signal RQBCN is asserted, Immediate Requests are serviced from the Beacon State. RQCLM and RQBCN do not cause transitions to the Claim and Beacon States.

On Transmit, frames are checked to see that they are of a minimum length. If the end of a frame is reached before a valid length is transmitted, the frame will be aborted and a Void frame will be transmitted (as with all aborted frames). A MAC frame with a zero length INFO field will not be aborted even though the Receiver will not recognize it as a valid frame. Frame lengths are not checked for the maximum allowable length (4500 bytes).

TABLE 5-4. Valid Frame Length

Frame Types	Short Address	Long Address	Notes
	(minimum number of bytes)		
Void	9	17	
MAC	13	21	including a 4 byte INFO field
non-MAC	9	17	including a 0 byte INFO field

Also on the Transmit side, the L bit in the FC field is checked against the ESA and ELA bits in the Option Regis-

ter (if the SA Transparency option is not selected) to insure that a frame of that address length can be transmitted. If the selected address length is not enabled, the frame is aborted at the beginning of the SA field. If SA Transparency is selected, the frame is not aborted.

When Option.IRPT is set and SAT and SAIGT are selected or when Mode.DIAG is set, the minimum frame length is one data byte.

5.5 FRAME STATUS PROCESSING

Each frame contains three or more Control Indicators. The FDDI Standard specifies three: the E, A, and C Indicators.

When a frame is transmitted, the Control Indicators are transmitted as R (Reset) symbols. If an error is detected by a station that receives the frame, the E Indicator is changed to an S (Set) symbol. If a station recognizes the DA of a frame as its own address (Individual, Group, or Broadcast), the A Indicator is changed to an S symbol. If that station then copies the frame, the C Indicator is changed to an S symbol.

The received value of the Control Indicators for every frame received is reported at the MAC Indicate Interface on signals MID(7-0). On a frame transmitted by this station, the returning Control Indicators give the transmission status.

5.0 Functional Description (Ring Engine) (Continued)

The Ending Delimiter followed by the Frame Status Indicators should begin and end on byte boundaries. Control Indicators are repeated until the first non R, S, or T symbol is received.

The processing of properly aligned E, A and C indicators by the Ring Engine is detailed in Table 5-5. Given the shown received Control Indicator values and the settings of the internal flags, the noted control indicator values will be transmitted.

5.5.1 Odd Symbols Handling

When the first T symbol of a frame is received as the second symbol of a symbol pair (the T symbol is received off-boundary), the Ring Engine signals this condition by sending out the symbol sequence TSII. This indicates the end of frame for a frame which had an error. Note that this is a low probability error event.

Reception of symbols other than R, S, or T during the Frame Status processing is also a low probability event.

5.6 SMT FRAME PROCESSING

All SMT frames are handled as all other frames with the exception of the SMT Next Station Addressing (SMT NSA) frame. NSA frames are used to announce this station's address to the next addressed station. The current SMT protocol requires stations to periodically (at least once every 30 seconds) transmit an NSA frame. Since the Broadcast address is used, and every station is required to recognize the broadcast address, the downstream neighbor will set the A Indicator. A station can determine its upstream neighbor by finding NSA frames received with the A Indicator received as R. By collecting this information from all stations, a map of the logical ring can be built.

TABLE 5-5. Control Indicator Processing

Received Indicators			Flags				Transmitted Indicators		
E	A	C	E	A	Copy	N	E	A	C
R	R	R	0	0	X	X	R	R	R
R	R	R	0	1	0	X	R	S	R
R	R	R	0	1	1	X	R	S	S
X	R	R	1	X	X	X	S	R	R
R	R	S	0	0	X	X	R	R	S
R	R	S	0	1	0	X	R	S	R
R	R	S	0	1	1	X	R	S	S
X	R	S	1	X	X	X	S	R	S
R	S	R	0	X	X	1	R	S	R
R	S	R	0	X	0	0	R	S	R
R	S	R	0	1	1	0	R	S	R
R	S	R	0	0	X	X	R	S	S
R	S	S	0	X	X	X	R	S	S
X	S	S	1	X	X	X	S	S	S
R	R	T	0	0	X	X	R	R	T
R	R	T	0	1	0	X	R	S	R
R	R	T	0	1	1	X	R	S	S
X	R	T	1	X	X	X	S	R	T
R	S	T	0	1	1	0	R	S	S
R	S	T	0	0	X	X	R	S	T
R	S	T	0	1	0	X	R	S	R
R	S	T	0	1	1	1	R	S	R
X	S	T	1	X	X	X	S	S	T

E_Flag is set when the local FCS check fails or when the E Indicator is received as anything other than R.

A_Flag is the value of the internal A_Flag or the external A_Flag as indicated by the EA input signal (when Option.Emind is set).

EC represents the value of the External C indicator Input Signal one byte time before then ending delimiter of the frame.

The Copy Flag is a one cycle delayed version of the VCOPY input.

N_Flag indicates that an NSA frame is being received. This signal is sampled at the same time that the received A indicator is being investigated.

X Represents a Don't Care Condition.

5.0 Functional Description (Ring Engine) (Continued)

Additionally, only the station that sets the A Indicator is permitted to set the C Indicator on such frames. In this way, the station that sends out the NSA frame can determine if the next addressed station copied the frame by examining the returning C Indicator.

5.7 MAC FRAME PROCESSING

Upon the reception of a valid MAC frame (Claim, Beacon, or Other), the Ring_Operational flag is reset and the Ring Engine enters the Idle, Claim or Beacon State. Received Claim and Beacon frames are processed as defined in the MAC Standard, unless explicitly inhibited by the bits in the Option Register (e.g., Inhibit Recovery Required).

5.7.1 Claim Token Process

Receive

When a Claim frame is received, its Frame Type is reported (Claim frame) along with the type of Claim frame.

There are three types of Claim frames: My_Claim, Higher_Claim, and Lower_Claim.

A My_Claim frame is a Claim frame with a Source Address that matches this station address and the T_Bid_Rc in the INFO field is equal to this station's TREQ.

A Higher_Claim frame is a Claim frame with a Source Address that does not match this station address and the T_Bid_Rc in the INFO field is greater than this station's TREQ.

A Lower_Claim frame is a Claim frame with a Source Address that does not match this station address and the T_Bid_Rc in the INFO field is smaller than this station's TREQ.

Transmit

Claim frames are transmitted continuously while in the Tx_Claim State.

Claim frames are generated by the Ring Engine unless an Immediate Claim Request is present at the MAC Request Interface. Even if an Immediate Claim Request is present at the MAC Request Interface, at least one Claim frame must be generated by the Ring Engine before Claim frames from the Interface are transmitted.

For internally generated Claim frames, the Information field is transmitted as the 4-byte Requested Target Token Rotation Time.

The Information field of a Claim frame consists of this station's Requested Target Token Rotation Time. In the Ring Engine implementation, TREQ is programmable with a 20.48 μ s resolution and a maximum value of 1.34 seconds.

Claim Protocol

Entry to the Tx_Claim state occurs whenever token recovery is required. The Recovery Required condition occurs when:

- TRT expires and Late_Flag is set
- TVX expires
- A Lower Claim frame or My_Beacon frame is received

Entry to the TX_Claim state may be blocked by enabling the Inhibit Recovery Required option (bit Option.IRR).

The Tx_Claim state is entered (even if Option.IRR = 1) with an SM_MA_Control.request(Claim) which is accomplished by setting Function.CLM to 1.

While in the Tx_Claim state:

- Claim frames are transmitted continuously
- If a Higher_Claim frame is received, the station exits the Claim state and enters the IDLE state. In this state it then repeats additional Higher_Claim frames.
- If a Lower_Claim frame is received, this station continues to send its own Claim frames and remains in the Claim state.

Eventually, if a logical ring exists, the station with the shortest TREQ on the ring should receive its own Claim frames, the My_Claim frame. This completes the Claim Token Process. This one station then earns the right to issue a token to establish an Operational ring.

An option is provided to remain in the Claim state if this station won the Claim Token Process by enabling the Inhibit Token Release Option (bit Option.IRR).

5.7.2 Beacon Process

Receive

When a Beacon frame is received, its Frame Type is reported (Beacon frame) along with the type of Beacon frame.

There are two types of Beacon frames: My_Beacon and Other_Beacon.

A Beacon frame is considered a My_Beacon if its Source Address matches this station's address (long or short).

A Beacon frame is marked as Other_Beacon if its Source Address does not match this station's address.

Transmit

Beacon frames are transmitted continuously while in the Tx_Beacon state.

Beacon frames are generated by the Ring Engine, unless an Immediate Beacon Request is present at the MAC Request Interface. Even if an Immediate Beacon Request is present at the MAC Request Interface, at least one Beacon frame must be generated by the Ring Engine before Beacon frames from the Interface are transmitted.

For internally generated Beacon frames, the Ring Engine uses the TBT in the Information field.

Beacon Protocol

Entry to the Tx_Beacon state occurs under two conditions:

- A failed Claim Process (TRT expires during the Claim process)
- An SM_MA_Control.request(Beacon) which is accomplished by setting Function.BCN to 1).

Beacon frames are then transmitted until the Beacon process is completed.

If an Other_Beacon frame is received, this station exits the Beacon state, stops sending its own Beacon frames, and repeats the incoming Beacon frames.

If a My_Beacon frame is received, the station has received back its own Beacon frame; thus successfully completing the Beacon process. The station then enters the Claim Process.

5.0 Functional Description (Ring Engine) (Continued)

5.7.3 Handling Reserved MAC Frames

A Reserved MAC frame is any MAC frame aside from Beacon and Claim frames. Tokens are not considered MAC frames even though their Format bit (FC.FF) is the same as for MAC frames.

When a Reserved MAC frame (Other__MAC) is received, it is treated as a Higher Claim. If the Transmitter is in the Claim state when a Reserved MAC frame is received, the Transmitter returns to the Idle state and then repeats the next Reserved MAC frame received. If the Transmitter is in the Beacon state and a Reserved MAC frame is received, the Transmitter continues to transmit Beacon frames. If the Transmitter is in the Idle state, the Reserved MAC frame is repeated.

5.8 RECEIVE BATCHING SUPPORT

The Ring Engine stores each received SA and compares the incoming SA with the previous SA. This may be used to batch status on frames received from the same station.

The SameSA signal is asserted when:

1. The current and previous non-Void frames were not MAC frames.
2. The size of the address of the current frame is the same as the size of the address of the previous non-Void frame.
3. The SA of the current frame is the same as the SA of the previous non-Void frame.

On MAC frames, the Information fields are compared. This information may be useful to inhibit copying MAC frames with identical information. This is particularly useful for copying Claim and Beacon frames when new information is present.

The Same INFO signal is asserted when:

1. The current and previous non-Void frames were both MAC frames (not necessarily the same FC value).
2. The first four bytes of the INFO field of the current frame is the same as the first four bytes of the INFO field of the previous non-Void frame.

The size of the address of MAC frames is not checked.

5.9 IMMEDIATE FRAME TRANSMISSION

Immediate requests are used when it is desirable to send frames without first capturing a token. Immediate requests are typically used as part of management processes for Error Isolation and Recovery. Immediate requests are also useful in full duplex applications. Immediate requests are serviced only when the station's Ring__Operational flag is Zero (CTSR.ROP = 0).

To transmit an Immediate request, the request must first be queued at the MA__Request Interface. If the Ring is not operational (Ring__Operational flag is not set), the request will be serviced immediately. If the Ring is operational (Ring__Operational flag is set), the request will be serviced when the Ring becomes non-operational. The Ring becomes non-operational as a result of a MAC Reset (Function.MCRST is set to One) or any of the conditions causing the Reset or Recovery Actions to be performed.

In addition to servicing an Immediate request from the Tx__Data State, it is also possible to service Immediate requests from the Tx__Claim or Tx__Beacon State. When transmitting from the Claim or Beacon state, in addition to requesting an Immediate Transmission Service Class, the RQCLM or RQBCN signals must be asserted to indicate an Immediate Claim or Immediate Beacon request. These requests will only be serviced when in the Claim or Beacon state. Entry to the Tx__Beacon State can be forced by setting bit BCN of the Function Register to One. Entry to the Tx__Claim State can be forced by setting bit CLM of the Function Register to One.

While in the Tx__Claim or Tx__Beacon state, the Ring Engine will transmit internally generated Claim or Beacon frames except when an Immediate Claim or Beacon request is present at the MA__Request Interface, signal RQCLM or RQBCN is asserted, and a frame is ready to be transmitted. At least one internally generated Claim or Beacon frame must be transmitted before an Immediate Claim or Beacon request is serviced. It is possible for the internally generated frame to return before the end of the requested frame has been transmitted. To allow time for the requested frame(s) to be transmitted before leaving the Claim or Beacon state, bit ITR (for Claim) or bit IRR (for Beacon) of the Option Register should be set to One.

While an Immediate request is being serviced (from any state), if bit IRPT of the Option Register is set to One (Inhibit Repeat option), all received frames (except Lower__Claim and My__Beacon frames) are ignored and the Immediate request continues. Lower__Claim and My__Beacon frames can also be ignored by setting bit IRR of the Option Register.

5.10 FULL DUPLEX OPERATION

The Ring Engine supports full duplex operation by

1. Suspending the Token Management and Token Recovery protocols (set Option.IRR).
2. Inhibiting the repetition of all frames and tokens (set Option.IRPT).
3. Using the Immediate Service Class.

Frames of any size may be transmitted or received, subject to the minimum length specified in Section 5.4.

5.11 PARITY PROCESSING

Through Parity is supported on the internal data paths between any Request interface and any Indicate interface.

Odd Parity is provided every clock on all data outputs and is checked every clock on all data inputs. Parity errors are not propagated through the Ring Engine (from the MAC Request and PHY Indication interface to the PHY Request interface or from the PHY Indication interface to the MAC Indication interface). Parity errors are isolated and resolved.

When parity is not used on an Interface, the parity provided by the Ring Engine for its outputs may be ignored. For the Ring Engine's inputs, the result of the parity check is used only if parity on that Interface is enabled.

Interface parity is enabled by setting the appropriate bit in the Mode register: Mode.CBP for Control Bus Parity, Mode.PIP for PHY Indication parity and Mode.MRP for MAC Request Parity. A Master Reset (Function.MARST) disables parity on all interfaces.

5.0 Functional Description (Ring Engine) (Continued)

On the PHY Request interface, parity is generated for internally sourced fields (such as the SA or FCS on frames when not using SA or FCS transparency, and internally generated Beacon, Claim and Void frames). Odd parity is always generated for PRP. This allows through parity support at the PHY interface even if parity is not used at the MAC interface. This is very desirable since every byte of data that traverses the ring travels across the PHY Interface which is actually part of the ring.

Through parity is not supported in the Control Interface Registers and the Parameter RAM. Parity is generated and stripped at the Control Interface.

Handling Parity Errors

Parity errors are reported in the Exception Status Register when parity on that interface is enabled.

A parity error at the PHY interface (when Mode.PIP is set) is treated as a code violation and ESR.PPE is set. If the parity error occurs in the middle of token or frame reception, the token or frame is stripped, a Format Error is signalled (FOERROR) and the Lost Count is incremented.

A parity error at the MAC Interface (when Mode.MRP is set) during a frame transmission from the MAC interface (while TXACK is asserted) causes the frame transmission to be aborted. When a frame is aborted, a Void frame is transmitted to reset every station's TVX timer. A parity error (when enabled) causes ESR.MPE to be set.

A parity error at the Control Interface (when Mode.CBP is set) will cancel the current write access. ESR.CPE is set to indicate that a parity error occurred and ESR.CCE is set to indicate that the write was not performed.

5.12 HANDLING INTERNAL ERRORS

Errors internal to the Ring Engine cause a MAC Reset. This includes detecting illegal states in the state machines. Internal Errors are reported in the Internal Error Latch Register (IELR). After an internal state machine error is detected and reported (IELR.RSMERR for the receiver and IELR.TSMERR for the transmitter), the current state registers continue to be updated as always.

In diagnose mode, the Current Receive and Transmit Status Registers are frozen with the errored state until the internal state machine error condition is cleared (IELR.RSMERR and/or IELR.TSMERR).

6.0 Functional Description (Service Engine)

6.1 OVERVIEW

The Service Engine consists of two major blocks: the Indicate Machine and the Request Machine. These blocks share the Bus Interface Unit, Status/Space Machine, Pointer RAM, and Limit RAM blocks.

The Service Engine provides an interface between the Ring Engine FDDI Media Access Control Protocol block and a host system. The Service Engine transfers FDDI frames between the FDDI device and host memory.

6.1.1 Indicate Machine

On the Receive side (from the ring) the Indicate Machine sequences through the incoming byte stream from the Ring Engine. Received frames are sorted onto Indicate Channels and a decision is made whether or not to copy them to host memory. The Indicate Machine uses the control signals provided by the Ring Engine Receive State Machine on the MAC Indicate Interface to make this decision.

6.1.2 Request Machine

On the Transmit side (to the ring) the Request Machine prepares one or more frames from host memory for transmission to the Ring Engine. The Request Machine provides all the control signals to drive the Ring Engine Request Interface.

6.2 OPERATION

6.2.1 Indicate Operation

The Indicate Block accepts data from the Ring Engine as a byte stream.

Upon receiving the data, the Indicate Block performs the following functions:

- Decodes the Frame Control field to determine the frame type
- Sorts the received frames onto Channels according to the Sort Mode
- Optionally Filters identical MAC frames
- Filters Void frames
- Copies the received frames to memory according to Copy Criteria
- Writes status for the received frames to the Indicate Status Queue
- Issues interrupts to the host on host-defined status breakpoints

The Indicate Machine decodes the Frame Control (FC) field to determine the type of frame. The following types of frames are recognized: Logical Link Control (LLC), Restricted Token, Unrestricted Token, Reserved, Station Management (SMT), SMT Next Station Addressing, MAC Beacon, MAC Claim, Other MAC, and Implementer.

The Indicate Machine sorts incoming frames onto Indicate Channels according to the frame's FC field, the state of the AFLAG signal from the Ring Engine (which indicates that the MACSI device had an internal address match), and the host-defined sorting mode programmed in the Sort Mode field of the Indicate Mode Register. SMT and MAC frames are always sorted onto Indicate Channel 0. On Indicate Channels 1 and 2, frames can be sorted according to whether they are synchronous or asynchronous, or whether they are high-priority asynchronous or low-priority asynchronous. Frames can also be sorted by whether their address matches an internal (MACSI device) or external address, or based on header and Information fields for all non-MAC/SMT frames.

The Synchronous/Asynchronous Sort Mode is intended for use in end-stations or applications using synchronous transmission.

6.0 Functional Description (Service Engine) (Continued)

With High-priority/Low-priority sorting, high-priority asynchronous frames are sorted onto Indicate Channel 1 and low-priority asynchronous frames are sorted onto Indicate Channel 2. The most-significant bit of the three-bit priority field within the FC field determines the priority. This Mode is intended for end stations using two priority levels of asynchronous transmission. Synchronous frames are sorted to Indicate Channel 1 in this mode.

With External/Internal sorting, frames matching the internal address (Individual or Group addresses in the MACSI device) are sorted onto Indicate Channel 1 and frames matching an external address (when the ECOPY input is asserted) are sorted onto Indicate Channel 2. Note that under some conditions it is possible to sort internal address match and SMT/MAC frames to Indicate Channel 2. Please see Section 6.3 for full details on the External Matching Interface. This sort mode is intended for bridges or ring monitors, which would use the ECIP/ECOPY/EM pins with external address matching circuitry. However, designers should be aware of the functioning of the ECIP pin even if external matching will not be used. If ECIP is left in an improper state (e.g., floating or tied high), it will affect the operation of the MACSI device even when External/Internal sorting is not enabled.

With the Header/Info Sort Mode, Indicate Channels 1 and 2 receive all non-MAC/SMT frames that are to be copied, but between them split the frame header (whose length is user-defined) and the remaining portions of the frame (Info). Indicate Channel 1 copies the initial bytes up until the host-defined header length is reached. The remainder of the frame's bytes are copied onto Indicate Channel 2. Only one IDUD stream is produced (on Indicate Channel 1), but both Pool Space Pointer (PSP) Queues are used to determine where the IDUs will be written. When a multi-part IDUD is produced, the Indicate Status field is used to determine which parts point to the header and which point to the Info. This Mode is intended for high-performance protocol processing applications.

The Indicate Machine filters identical MAC and SMT frames when the SKIP bit in the Indicate Mode Register is set and the Indicate Configuration Register's Copy Control field (2 bits) for Indicate Channel 0 is set to 01 or 10.

Received frames are copied to memory based on the AFLAG, MFLAG, ECIP, ECOPY, and EM input signals from external address matching logic, control signals from the Ring Engine, as well as the Indicate Channel's Copy Control field. Received frames are written as a series of Input Data Units to the current Indicate memory page defined by the host via a PSP. Each frame is aligned to the start of a currently-defined burst-size memory block (16 or 32 bytes as programmed in the Mode Register's SMLB bit). The first word written contains four copies of the FC byte. The IDUD pointer points to the last FC byte so that host software sees only a single FC byte as expected. The extra FC bytes have the advantage of causing the INFO field to be aligned to a 32-bit word boundary. The format differs according to the setting of the Mode Register's BIGEND (Big Endian) bit, as shown in *Figure 6-1*.

Byte 0		Byte 3	
Bit 31	Big Endian Indicate Data Unit Format		Bit 0
FC	FC	FC	FC
DA0	DA1	SA0	SA1

Byte 3		Byte 0	
Bit 0	Little Endian Indicate Data Unit Format		Bit 31
FC	FC	FC	FC
SA1	SA0	DA1	DA0

FIGURE 6-1. Indicate Data Unit Formats (Short Address)

For each Input Data Unit, the Indicate Machine creates an Input Data Unit Descriptor (IDUD), which contains status information about the IDU, its size (byte count), and its location in memory. For IDUs that fit within the current Indicate memory page, an IDUD.Only Descriptor is created. For IDUs that span more than one memory page, a multi-part IDUD is created. For example, when a frame crosses a page boundary, the MACSI device writes an IDUD.First. If another page is crossed, an IDUD.Middle will be written. At the frame end, an IDUD.Last is written. IDUDs are written to consecutive locations in the Indicate Status Queue for the particular Indicate Channel, up to the host-defined queue limit.

The MACSI device has two modes for storing IDUs into Pool Space Pages. In the first mode, the MACSI device will assemble as many frames into a 4 kByte page as will fit. Thus, a single page of Pool Space memory may contain multiple frames and have many IDUDs pointing to it. In the second mode, the MACSI device forces a page break after the end of each frame. This means that a single page of Pool Space memory will have at most a single IDUD pointing to it. This mode greatly simplifies space reclamation in those systems which do not process incoming frames in order of receipt and supports systems in which the cache line size is greater than 32 bytes.

The Indicate Machine copies IDUs and IDUDs to memory as long as there are no exceptions or errors and the Channel has data and status space. When a lack of either data or status space is detected on a particular Channel, the Indicate Machine stops copying new frames for that Channel (only). It will set the No Status Space attention bit in the No Space Attention Register when it runs out of Status Space. It will set the Low Data Space bit in the No Space Attention Register when the last available PSP is prefetched from the Indicate Channel PSP Queue. The host allocates more data space by adding PSPs to the tail of the PSP Queue and then updating the PSP Queue Limit Register, which causes the MACSI device to clear the Low Data Space attention bit and resume copying (on the same Channel). The user should **never** clear the Low Data Space attention bits directly. The host allocates more status space by updating the IDUD Queue Limit Register and then explicitly clearing the Channel's No Status Space bit, after which the Indicate Machine resumes copying. Note that the No Status Space Attention bit must be cleared **after** the appropriate limit register is updated.

6.0 Functional Description (Service Engine) (Continued)

The MACSI device provides the ability to group incoming frames and then generate interrupts (via attentions) at group boundaries. To group incoming frames, the MACSI device defines status breakpoints, which identify the end of a group (burst) of related frames. Status breakpoints can be enabled to generate an attention.

The breakpoints for Indicate Channels are defined by the host in the Indicate Mode, Indicate Notify, and Indicate Threshold registers. Status breakpoints include Channel change, receipt of a token, SA change, DA change, MAC Info change, or a user-specified number of frames have been copied on a particular Indicate Channel.

Status breakpoint generation may be individually enabled for Indicate Channels 1 and 2 by setting the corresponding Breakpoint bits (Breakpoint on Burst End, Breakpoint on Service Opportunity, and Breakpoint on Threshold) in the Indicate Mode Register, and enabling the breakpoints to generate an attention by setting the corresponding Breakpoint bit in the Indicate Notify Register.

When an Indicate exception occurs, the current frame is marked complete, status is written into an IDUD.Last, and the Channel's Exception (EXC) bit in the Indicate Attention Register is set.

When an Indicate error (other than a parity error) is detected, the Error (ERR) bit in the State Attention Register is set. The host must reset the INSTOP Attention bit to restart processing.

When parity checking is enabled and a parity error is detected in a received frame, it is recorded in the Indicate Status field of the IDUD, and the Ring Engine Parity Error (REPE) bit in the Status Attention Register is set.

A frame which is stripped after the fourth byte of the Information Field (this may occur because an upstream station detected an error within the frame) will be copied to memory but the status will show that the frame was stripped.

6.2.2 Request Operation

The Request Block transmits frames from host memory to the Ring Engine. Data is presented to the Ring Engine as a byte stream.

The Request Block performs the following functions:

- Prioritizes active requests to transmit frames
- Requests the Ring Engine to obtain a token
- Transmits frames to the Ring Engine
- Writes status for transmitted and returning frames
- Issues interrupts to the host on user-defined group boundaries

The Request Machine processes requests by first reading Request Descriptors from the REQ Queue and then assembling frames of the specified service class, Frame Control (FC) and expected status for transmission to the Ring Engine. Request and ODU Descriptors are checked for consistency and the Request Class is checked for compatibility with the current ring state. When an inconsistency or incompatibility is detected, the request is aborted.

When a consistency failure occurs, the Request is terminated and a Confirmation Descriptor (CNF) with the appropriate status is generated. The Request Machine then locates the end of the current object (REQ or ODU). If the current

Descriptor is not the end (Last bit not set), the Request Machine will fetch subsequent Descriptors until it detects the end and then resume processing with the next Descriptor.First or Descriptor.Only.

Requests are processed on both Request Channels simultaneously. Their interaction is determined by their priorities (Request Channel 0 has higher priority than Request Channel 1) and the Hold and Preempt/Prestage bits in the Request Channel's Request Configuration Register. An active Request Channel 0 is always serviced first, and may be programmed to preempt Request Channel 1, such that uncommitted Request Channel 1's data already in the request FIFO will be purged and then refetched after servicing Request Channel 0. When prestaging is enabled, the next frame is staged before the token arrives. Prestaging is always enabled for Request Channel 0, and is a programmable option on Request Channel 1. The MACSI device will process at most one Request per Channel per Service Opportunity.

The MACSI device contains an option bit which controls the timing of Token capture. This bit is the Early Token Request bit (ETR) which is in R0CR1 (for Request Channel 0) and R1CR1 (for Request Channel 1). When the ETR bit is disabled for a channel, the MACSI device will fetch a Request descriptor and then fetch the first ODU and begin filling the transmit FIFO for that channel. When the FIFO threshold is reached (R0CR0.TT or R1CR0.TT) the MACSI device presents a Request Class to the Ring Engine which causes the Ring Engine to capture a Token of the specified class.

When the ETR bit is enabled, a REQ.First is loaded, the Request Machine commands the Ring Engine to capture a token of the type specified in the REQ Descriptor, and concurrently fetches the first ODU. This mode is useful for systems which need tight control of the Token capture timing (e.g., systems using Synchronous traffic). Note that use of the Early Token Request mechanism may, under certain circumstances, waste ring bandwidth (i.e., holding the Token while filling the FIFO). Therefore, it should be enabled only in those systems where the feature is specifically required.

If prestaging is enabled or a Service Opportunity exists for this Request Channel, data from the first ODU is loaded into the Request FIFO, and the MACSI device requests transmission from the Ring Engine. When the Ring Engine has captured the appropriate token and the frame is committed to transmission (the FIFO threshold has been reached or the end of the frame is in the FIFO), transmission begins. The MACSI device fetches the next ODU and starts loading the ODUs of the next frame into the FIFO. This continues (across multiple service opportunities if required) until all frames for that Request have been transmitted (i.e., an REQ.ONLY or an REQ.LAST is detected) or an exception or error occurs which prematurely ends the Request.

The MACSI device will load REQ Descriptors as long as the RQSTOP bit in the State Attention Register is Zero, the REQ Queue contains valid entries (the REQ Queue Pointer Register does not exceed the REQ Queue Limit Register), and there is space in the CNF Queue (the MACSI device has not detected equality of the CNF Queue Pointer Register and the CNF Queue Limit Register).

6.0 Functional Description (Service Engine) (Continued)

Request status is generated as a single confirmation object (single- or multi-part) per Request object, with each confirmation object consisting of one or more CNF Descriptors. The type of confirmation is specified by the host in the Confirmation Class field of the REQ Descriptor.

The MACSI device can be programmed to generate CNF Descriptors at the end of the Request object (End Confirmation), or at the end of each token opportunity (Intermediate Confirmation), as selected in the E and I bits of the Confirmation Class Field of the REQ Descriptor. A CNF Descriptor is always written when an exception or error occurs (regardless of the value in the Confirmation Class field), when a Request is completed (for End or Intermediate Confirmation Class), or when a Service Opportunity ends (Intermediate Confirmation Class only).

There are three basic types of confirmation: Transmitter, Full, and None. With Transmitter Confirmation, the MACSI device verifies that the Output Data Units were successfully transmitted. With Full Confirmation, the Request Machine verifies that the ODUs were successfully transmitted, that the number of (returning) frames “matches” the number of transmitted ODUs, and that the returning frames contain the expected status. Full confirmation takes advantage of the fact that the sending station also removes its frames from the network. When the None Confirmation Class is selected, confirmation is written only if an exception or error occurs.

For Full Confirmation, a matching frame must meet the following criteria:

1. The frame has a valid Ending Delimiter (ED).
2. The selected bits in the FC fields of the transmitted and received frames are equal (the selected bits are specified in the FCT bit of the Request Configuration Register).
3. The frame is My__SA (MFLAG or both SAT & EM asserted).
4. The frame status indicators match the values in the Expected Frame Status Register.
5. FCS checking is disabled or FCS checking is enabled and the frame has a valid FCS.
6. All bytes from FC to ED have good parity (when the FLOW bit in the Mode Register is set, i.e., parity checking is enabled).

The confirmed frame count starts after the first Request burst frame has been committed by the Ring Engine, and when a frame with My__SA is received. Void and My__Void frames are ignored by the MACSI device. The frame count ends when any of the following conditions occur:

1. All frames have been transmitted, and the transmitted and confirmed frame counts are equal.
2. There is a MACRST (MAC Reset).
3. The state of the ring-operation has changed.
4. A stripped frame or a frame with a parity error is received.
5. A non-matching frame is received.
6. A token is received.

When Source Address Transparency is selected (by setting the SAT bit in the Request Configuration Register) and Full confirmation is enabled, confirmation begins when a frame end is detected with either MFLAG or EM asserted.

When a non-matching frame is received, the MACSI device ends the Request, and generates the Request Complete (RCM), Exception (EXC), and Breakpoint (BRK) attentions. Any remaining REQs in the Request object are fetched until a REQ.Last or REQ.Only is encountered. Processing then resumes on the next REQ.First or REQ.Only (any other type of REQ would be a consistency failure).

Request errors and exceptions are reported in the State Attention Register, Request Attention Register, and the Confirmation Message Descriptor. When an exception or error occurs, the Request Machine generates a CNF and ends the Request. The Unserviceable Request (USR) attention is set to block subsequent Requests once one becomes unserviceable.

6.2.3 State Machines

There are three state machines under control of the host: the Request Machine, the Indicate Machine, and the Status/Space Machine. Each Machine has two Modes: Stop and Run. The Mode is determined by the setting of the Machine's corresponding STOP bit in the State Attention Register. The STOP bits are set by the MACSI device when an error occurs or may be set by the user to place the state machine in Stop Mode.

The MACSI device Control Registers may be programmed only when all Machines are in Stop Mode. When the Status/Space Machine is in Stop Mode, only the Pointer RAM and Limit RAM Registers may be programmed. When the Indicate and Request Machines are in Stop Mode, all indicate and request operations are halted. When the Status/Space Machine is in Stop Mode, only the PTOp and LMOP service functions can be performed.

6.3 EXTERNAL MATCHING INTERFACE

This interface consists of five pins (six on MACSI revision D or later) that give the MACSI device additional status regarding address matches. Typical applications for this interface include address matching for Bridge and Router devices. The five pins include four inputs (ECIP, ECOPY, EA, and EM) and one output (LEARN). MACSI revisions D or later have an additional input pin (AFINHIB). ECIP provides timing information to the System Interface. ECOPY and EM provide status to the System Interface on external Destination and Source address matches respectively (most applications use ECOPY only). The Ring Engine uses EA and EM for setting the A Indicator and frame stripping.

For the purposes of external matching, it is recommended that the frame data be viewed at the PLAYER+ /MACSI Receive interface, (PID<7:0>, PIP, PIC). In addition it is recommended that the user design the circuit to detect the JK symbol at the MACSI/PLAYER+ interface to start address matching.

To instruct the MACSI device to copy a frame, the proper use of the ECIP, ECOPY, and EM pins is as follows. External address matching circuitry must assert ECIP some time from the arrival of the start delimiter (JK) to the 6th byte of the INFO field (as measured at the PLAYER+ /MACSI interface). Otherwise, the MACSI device assumes that no external address comparison is taking place. ECIP must be negated for at least one cycle to complete the external comparison. If it has not been deasserted by the 2nd byte after the End Delimiter (ED), the frame is not copied. ECOPY and EM are sampled on the clock cycle after ECIP is negated. ECIP is ignored after it is negated until the arrival of the next JK.

6.0 Functional Description (Service Engine) (Continued)

TL/F/11705-8

FIGURE 6-2. MACSI Device External Matching Interface Timing

Note that this design allows ECIP to be a positive or negative pulse. To confirm frames in this mode, (typically with Source Address Transparency enabled), EM must be asserted within the same timeframe as ECOPY.

The Ring Engine samples EA two byte-times after the end delimiter (ED) is passed between the PLAYER+ device and the MACSI device. If EA is asserted, the MACSI device will transmit the A Indicator as an S. The Ring Engine samples EM continuously and will begin to strip a frame three byte-times after the assertion of EM. This implies that the user must ground EM if not used. The Ring Engine does not use the ECIP timing signal.

It is important to note that ECIP functions as an indicator to the internal MACSI device Indicate Machine to hold off the copying of incoming data until the ECIP line is negated. Therefore, even if a design does not intend to take advantage of the MACSI device External Address Matching interface, the user must still ensure that the ECIP signal line is properly negated. Also important is the fact that the MACSI device samples the ECIP signal line in order to detect just two conditions. It looks at whether ECIP is asserted at any time during the period between the start delimiter (JK) and the 6th byte of the INFO field and then waits until the deassertion of ECIP, at which point the MACSI device samples the ECOPY and EM signal lines for their status on this particular frame.

In the timing diagram (see Figure 6-2), the specific cycles shown for the assertion and deassertion of ECIP comprise only one possible valid timing. Other timings are valid as well, within the limits of the timing parameters to be described below. Shaded areas indicate cycles where the MACSI device is not sampling the signal lines for this particular pattern. Note that the sampling of ECIP is level sensitive and synchronous with LBC1.

Note that there are five timing parameters (T1–T5). T1 and T3 are limits as to when the initial assertion of ECIP will be recognized. Once ECIP is asserted, T2, T4, and T5 become timing limits on the deassertion of ECIP. Once deasserted, ECIP is not sampled further (until the start of the next frame).

T1 is the earliest cycle where the assertion of ECIP will be recognized. ECIP may be asserted earlier than this but the

MACSI device will not sample it during these earlier periods. T1's timing is fixed as the fourth cycle following the FC data byte at the PLAYER+ /MACSI interface.

T2 is the earliest cycle where the deassertion of ECIP will be recognized. This can occur as soon as one cycle following ECIP's assertion. ECIP needs to be asserted for a minimum of one full clock cycle.

T3 is the latest cycle where the initial assertion of ECIP will still be recognized. T3 must occur before the 6th byte of the INFO field, not afterward. If ECIP is asserted later than this cycle, an external match will not be recognized; i.e., the frame will be copied only if it is an internal match. When ECIP is not asserted until after T3, it is not recognized. This is the only case where maintaining ECIP's assertion during the frame will have no effect at all.

T4 is the latest cycle where the deassertion of ECIP will be recognized in "regular" fashion. That is, if ECIP is held asserted beyond T4, a special case is created within the MACSI device when the external compare has persisted to the point where it takes precedence over all other copy modes. In this case, all frames which are copied, regardless of whether it was an external match, internal match, or SMT frame, **are copied to ICHN2**. Note that even if an internal match has already occurred, ECIP must still become deasserted for the frame copy to complete.

It is important to note that the timing shown for T4 is dependent on the setting of the SMLB bit of the MACSI device's System Interface Mode Register 0 (SIMR0). The timing shown in Figure 6-2 is for frame copies in small-burst mode only. T4 signifies the boundary condition internal to the MACSI device where the first full burst of data has been received. The ABus write access for this data will then automatically default to ICHN2 if an external copy decision is still pending, **regardless of sort mode**. When the SMLB bit is not set, i.e., in large burst mode, T4 would occur 16 cycles later than shown in Figure 6-2.

T5 is the final cycle where the deassertion of ECIP can be recognized, and it occurs two cycles after the end delimiter (ED) is transferred between the PLAYER+ and MACSI devices. If ECIP is held high beyond this point, the frame will not be copied at all, **even if an internal match occurred**. Note that this is true even if Internal/External sorting is not

6.0 Functional Description (Service Engine) (Continued)

enabled. Therefore, for applications which do not use external address matching, ECIP should be tied low. Note also that if ECIP remains asserted to the point where the incoming frame data completely fills the MACSI device's Indicate Data FIFO (4608 bytes for a MACSI device), then the frame will be dropped due to a FIFO overrun.

The LEARN pin provides MAC state machine information and ring state information useful for building learning bridges. The Receive logic of a bridge may wish to avoid copying frames or learning the source address of frames put on the ring by this same bridge. However, use of the Source Address Transparency option (SAT) can make recognition of frames sourced by this bridge difficult. The LEARN pin provides a mechanism for the bridge to determine which frames and addresses it should copy/learn.

The MACSI device deasserts the LEARN pin under the following conditions:

1. Ring Non-Operational. The MACSI device will deassert the LEARN pin whenever the ring is Non-Operational.
2. The Transmitter is holding the Token. While this station holds the Token, the only valid frames it should receive (other than MAC frames which indicate a fault, or no-owner frames that should be ignored in this case), consist of those frames that this station sent. Therefore, the MACSI device deasserts the LEARN pin. (Actually, the MACSI deasserts LEARN whenever the MAC transmitter is in the "Repeat" state.)
3. For the duration of "My_Void Stripping". The My_Void Stripping mechanism allows the MACSI device to strip frames from the ring that it sent using Source Address Transparency. Before releasing the Token, the MACSI device releases two My_Void frames. It continues to strip until the Receiver recognizes at least one My_Void (or other MAC) frame. LEARN will remain low during My_Void stripping.
4. The Source Address field equals "My Long Address" (MLA). If the internal address matching logic recognizes the source address of the incoming frame as its own, the MACSI device will deassert the LEARN pin.
5. Frames using short (16-bit) address. The MACSI deasserts the LEARN pin for all frames that use 16-bit addresses (FC.L = 0). Learning bridges usually work with 48-bit addresses.

Thus, the MACSI device will only assert LEARN for 48-bit addressed frames that this station did not source (Source Address \neq MLA, and Not My_Void stripping) received while the ring is Operational.

External logic monitoring the LEARN pin must sample it at the appropriate point for each received frame. Measured at the MACSI/PLAYER+ interface (PID), the LEARN pin becomes valid at the 4th byte of the Information Field (INFO3). External logic may sample this pin at INFO3 or later.

The MACSI device may or may not assert the LEARN pin at the beginning of a frame (for the reasons given above) and LEARN may change state up to INFO3 at the PID interface. Normally, LEARN will remain stable during the body of a frame (up to the End Delimiter). However, a MAC Reset, a Master Reset, etc., may cause the MACSI to deassert the LEARN pin anywhere within a frame. The Designer should account for these exceptions when designing any logic that relies on the LEARN pin.

The AFLAG Inhibit ($\overline{\text{AFINHIB}}$, available on MACSI revision D and later) allows the User to suppress the internal Address matching signal between the MAC and System Interface. The MACSI will ignore the $\overline{\text{AFINHIB}}$ pin until the User sets the AFLAG Inhibit Enable bit of the MAC Mode Register 2 (MCMR2.AFIE). To block an internal address match, the User must assert the $\overline{\text{AFINHIB}}$ input before the 7th byte of the INFO field as measured at the PID interface.

Normally, internal matches take precedence over external matches. The User might use $\overline{\text{AFINHIB}}$ to defeat this precedence and steer a frame that matches both an internal and external address to the external sort channel. This pin also provides an easy mechanism for suppressing the matching of broadcast (and multicast) frames during bridging. For these applications the User may connect the LEARN pin directly to the $\overline{\text{AFINHIB}}$ pin. This will prevent internal address matches of any frame during My_Void stripping.

6.4 BUS INTERFACE UNIT

6.4.1 Overview

The ABus provides a 32-bit wide synchronous multiplexed address/data bus for transfers between the host system and the MACSI device. The ABus uses a bus request/bus grant protocol that allows multiple bus masters, supports burst transfers of 16 and 32 bytes, and supports virtual and physical addressing using fixed-size pages. The MACSI device is capable of operating directly on the system bus to main memory or connected to external shared memory.

All bus signals are synchronized to the master bus clock. The maximum burst speed is one 32-bit word per clock, but slower speeds may be accommodated by inserting wait states. The user may use separate clocks for the ring (FDDI MAC) and system (ABus) interfaces. The only restriction is that the ABus clock must be at least as fast as the ring clock (LBC). It is important to note that all ABus outputs change and all ABus inputs are sampled on the rising edge of AB_CLK.

The MACSI device has two major modes of ABus operation. The default, or "normal" mode, corresponds to the original BSI device and is completely backward compatible. The second mode is the Enhanced ABus mode. This mode is intended to reduce the logic required to interface to the SBus originally developed by Sun Microsystems, Inc. When the enhanced mode is selected, the MACSI device timing and interface signals are modified slightly to create a closer fit to the SBus. This lowers the cost and eases design of SBus FDDI adapter cards. This new mode is accessible by programming a mode bit in a register (MR1.EAM = 1). This bit is set to an inactive state upon reset to maintain backward compatibility with the original BSI device.

Addressing Modes

In the default ABus mode, The Bus Interface Unit has two Address Modes, as selected by the user: Physical Address Mode and Virtual Address Mode. In Physical Address Mode, the MACSI device emits the memory address and immediately begins transferring the data. In Virtual Address Mode, the MACSI device inserts two clock cycles and TRI-STATE® the address between emitting the virtual address and starting to transfer the data. This allows virtual-to-physical address translation by an external memory mapping unit (MMU).

6.0 Functional Description (Service Engine) (Continued)

The MACSI device has a mode for controlling the ABus Address Strobe ($\overline{AB_AS}$). In the default mode, $\overline{AB_AS}$ is driven active during the address cycle and remains low throughout the access. In the second mode (SIMR1.ASM = 1), $\overline{AB_AS}$ is driven active during the address cycle and driven inactive during the remainder of the access. This allows $\overline{AB_AS}$ to be used directly as a clock enable to the address latching device which reduces the number of external components.

In Enhanced ABus Mode (EAM), the MACSI device has fixed address timing which is similar to the Physical address timing described above. The SBUS MMU does not require extra cycles for the address translation.

The MACSI device interfaces to byte-addressable memory, but always transfers information in words. The MACSI device uses a word width of 32 data bits plus 4 (1 per byte) parity bits. Parity may be ignored.

Bus Transfers

The ABus supports single word accesses and 4-word and 8-word bursts. Simple reads and writes involve a single address and data transfer. Burst reads and writes involve a single address transfer followed by multiple data transfers. Burst sizes are selected dynamically by the MACSI device. The user can disable 8-word bursts by setting MR0.SMLB to a 1. This forces the MACSI device to use 1-word and 4-word transactions only.

The MACSI device provides the full de-multiplexed address during an access. This includes the word address for each word of a burst ($AB_A[4:2]$). To use the de-multiplexed addresses ($AB_A[4:2]$) on MACSI revisions A, B, or C, the Address Timing Mode bit (SIMR1.ATM) must be set equal to one. This causes the word address to come out in the same cycle as the word of data being accessed. The word addresses signals ($AB_A[4:2]$) may be used in the "look-ahead" mode (SIMR1.ATM = 0) if the user does address de-multiplexing externally by latching $AB_A[27:5]$ externally during the address cycle. For MACSI revisions D or later (SI revision $\geq 0x00000058$), the User may select either Address Timing Mode (SIMR1.ATM = 0 or 1) while using the demultiplexed address pins $AB_A[27:0]$.

On Indicate Channels, when 8-word bursts are enabled, all transactions will be 8 words until the end of the frame; the last transfer will be 4 or 8 words, depending on the number of remaining bytes. If only 4-word bursts are allowed, all Indicate Data transfers are 4 words.

On Request Channels, the MACSI device will use 4- or 8-word bursts to access all data up to the end of the ODU. If 8-word bursts are enabled, the first access will be an 8-word burst if the ODU begins less than 4 words from the start of an 8-word burst boundary. If 8-word bursts are not allowed, or if the ODU begins 4 or more words from the start of an 8-word burst boundary, a 4-word burst will be used. The MACSI device will ignore unused bytes if the ODU does not start on a burst boundary. At the end of an ODU, the MACSI device will use the smallest transfer size (1, 4, or 8 words) which completes the ODU read. To coexist in a system that assumes implicit wrap-around for the addresses within a burst, the MACSI device never emits a burst that will wrap the 4- or 8-word boundary.

A Function Code identifying the type of transaction is output by the MACSI device on the upper four address bits during the address phase of a data transfer. This can be used for more elaborate external addressing schemes such as directing control information to one memory and data to another (e.g., an external FIFO).

Byte Ordering

The basic addressable unit is a byte so request data may be aligned to any byte boundary in memory. All information is accessed in 32-bit words, however, so the MACSI device ignores unused bytes when reading.

Descriptors must always be aligned to a 32-bit word address boundary. Input Data Units are always aligned to a burst-size boundary. Output Data Units may be any number of bytes, aligned to any byte-address boundary but operate most efficiently when aligned to a burst-size boundary. Pool Space Descriptors (PSPs) **must** point to a burst boundary or the Receive data will not be written to memory correctly.

Burst transfers are always word-aligned on a 16- or 32-byte (burst-size) address boundary. Burst transfers will never cross a burst-size boundary. If a 32-byte transfer size is enabled (MR0.SMLB = 0), the MACSI device will perform both 16-byte and 32-byte bursts, whichever is most efficient (least number of clocks to load/store all required data). If the MACSI device has less than a full burst of data to complete a frame, it will write a full burst. Random data is written to the unused locations. The host uses the IDUD length field to determine where the valid data bytes end.

The Bus Interface Unit can operate in either Big Endian or Little Endian Mode. The bit and byte alignments for both modes are shown in *Figure 6-3*. Byte 0 is the first byte received from the ring or transmitted to the ring. This mode affects the placement of frame data bytes but it does not affect the order of Descriptor bytes.

Big-Endian Byte Order

D[31]		D[0]	
Word			
Halfword 0		Halfword 1	
Byte 0	Byte 1	Byte 2	Byte 3

Little-Endian Byte Order

Word			
Halfword 1		Halfword 0	
Byte 3	Byte 2	Byte 1	Byte 0

FIGURE 6-3. ABus Byte Orders

Bus Arbitration

The ABus is a multi-master bus, using a simple Bus Request/Bus Grant protocol that allows an external Bus Arbiter to support any number of bus masters, using any arbitration scheme (e.g., rotating or fixed priority). The protocol provides for multiple transactions per tenure and bus master preemption.

The MACSI device asserts a Bus Request, and assumes mastership when Bus Grant is asserted. If the MACSI device has another transaction pending, it will keep Bus Request asserted, or reassert it before the completion of the

6.0 Functional Description (Service Engine) (Continued)

current transaction. Note that Bus Request is guaranteed to be de-asserted for at least two cycles when MR1.EAM is enabled. It is a requirement of the SBus specification that Bus Request be de-asserted between each transaction. If Bus Grant is (re)asserted before the end of the current transaction, the MACSI device retains mastership and runs the next transaction. This process may be repeated indefinitely.

It is important to note that in default ABus mode (MR1.EAM = 0), the MACSI device may take up to two cycles to detect the assertion of Bus Grant. Therefore, the external interface logic must not remove Bus Grant or latch addresses until a signal such as Address Strobe is asserted indicating that the MACSI device has recognized the Bus Grant.

If the Bus Arbiter wishes to preempt the MACSI device, it deasserts Bus Grant. The MACSI device will complete the current bus transaction, then release the bus. From preemption to bus release is a maximum of (11 bus clocks + (8 times the number of memory wait states)) bus clocks. For example, in a 1 wait-state system, the MACSI device will release the bus within a maximum of 19 bus clocks.

Parity

The state of the FLOW bit in System Interface Mode Register 0 (SIMR0.FLOW) controls two MACSI device modes: one for systems using parity, the other for systems not using parity.

Regardless of the state of SIMR0.FLOW, the MACSI device always provides odd parity on ABus address cycles, and Control Bus read cycles. The MACSI device System Interface does not check data parity on ABus read cycles. The User may enable checking of read data parity at the Ring Engine interface by setting the MAC Request Parity bit (MCMR0.MRP). For MACSI revision D or later, the System Interface will check parity on descriptor reads (when SIMR0.FLOW = 1) and report errors via the STAR.ERR bit. The ABus data parity, (except for Descriptor data parity which is generated internally) flows directly from the Ring Engine interface. If parity checking is enabled within the Ring Engine, parity flows up from the PLAYER+ interface. If parity checking is disabled within the Ring Engine, good parity is generated at the Ring Engine/Service Engine interface.

For transmit frame data, the parity from the ABus flows directly to the Ring Engine interface when SIMR0.FLOW is asserted. The data integrity across the ABus and through the Service Engine may be checked by enabling parity checking within the Ring Engine. If the SIMR0.FLOW bit is deasserted, the MACSI device will generate good parity at the transmit data (MR7-0) Ring Engine interface.

When SIMR0.FLOW is enabled, parity is checked on Control Bus write operations. If a parity error is detected, the write access is rejected and the STAR.CPE bit is asserted. When SIMR0.FLOW is disabled Control Bus write parity is ignored.

When SIMR0.FLOW is enabled, parity is checked on MAC Indicate interface (receive data from the Ring Engine). If an error is detected, the STAR.BPE will be asserted and the IDUD for that frame will carry a status of "parity error". When SIMR0.FLOW is disabled, the parity bit at the MAC Indicate interface is ignored.

Bandwidth

The ABus supports single reads and writes, and burst reads and writes. With physical addressing, back-to-back single reads/writes can take place every four clock cycles. Burst transactions can transfer 8, 32-bit words (32 bytes) every 11 clock cycles. With a 25 MHz clock this yields a peak bandwidth of 72.7 Mbytes/sec.

To allow the bus to operate at high frequency, the protocol defines all signals to be both asserted and deasserted by the bus master and slaves. Having a bus device actively deassert a signal guarantees a high-speed inactive transition. If this were not defined, external pull-up resistors would not be able to deassert signals fast enough. The protocol also reduces contention by avoiding cases where two bus devices simultaneously drive the same line.

The MACSI device operates synchronously with the ABus clock. In general, operations will be asynchronous to the ring, since most applications will use a system bus clock that is asynchronous to the ring. The MACSI device is designed to interface either directly to the host's main system bus or to external shared memory. When interfaced to the host's bus, there are two parameters of critical interest: latency and bandwidth.

Data moves between the Request and Indicate Channels and the ABus via four FIFOs, two in the receive path (Indicate) and two in the transmit path (Request). There are two, 1152 x 36-bit data FIFOs for Indicate and Request data (4608 byte of data FIFO in each direction). On the ABus Interface, there are two Burst FIFOs, each containing two banks of 32 bytes which provide ABus bursting capability.

The amount of latency covered by the Data FIFO plus one of the banks of the Burst FIFO must meet the average and maximum bus latencies of the external memory. With a new byte every 80 ns from the ring, a 4608 byte FIFO provides $4608 \times 80 \text{ ns} = 368.64 \mu\text{s}$ maximum latency. The two 32 byte burst FIFO in each direction provide an additional 5.1 μs of latency.

To assist latency issues, the MACSI device can completely empty or fill the Burst FIFO in one bus tenure by asserting Bus Request for multiple transactions. Since one bank of the Burst FIFO is 8 words deep, if 8-word bursts are enabled, that half of the Burst FIFO can be emptied in one transaction. If the second half of the burst FIFO is also full, it can be emptied in the same bus tenure by again granting the bus to the MACSI device.

The MACSI device may be preempted at any time by removing Bus Grant, causing the MACSI device to complete the current transaction and release the bus. There will be a maximum of 11 clocks (plus any memory wait states) from preemption to bus release (fewer if 8-word bursts are not enabled).

6.4.2 Bus States

An ABus Master has eight states: idle (Ti), bus request (Tbr), virtual address (Tva), MMU translate (Tmmu), physical address (Tpa), data transfer (Td), wait (Tw) and recovery (Tr).

An ABus Slave has five states: idle (Ti), selected (Ts), data transfer (Td), wait (Tw), and recovery (Tr).

6.0 Functional Description (Service Engine) (Continued)

Master States

The Ti state exists when no bus activity is required. The BIU does not drive any of the bus signals when it is in this state (all are released). If the BIU requires bus service, it may assert Bus Request.

When a transaction occurs, the BIU enters Tbr, asserts Bus Request, and then waits for Bus Grant to be asserted.

The state following Tbr is either Tva or Tpa. In Virtual Address Mode, the BIU enters Tva and drives the virtual address and size lines onto the bus. In Physical Address Mode, Tpa occurs next (see Section 6.4.3).

Following a Tva state is a Tmmu state. During this cycle the external MMU is performing a translation of the virtual address emitted during Tva.

Following a Tmmu state (when using virtual addressing) or a Tbr state (when using physical addressing), is the Tpa state. During the Tpa state, the MACSI device drives the read/write strobes and size signals. In physical address mode, it also drives AB_AD with address. In virtual address mode, the MACSI device TRI-STATEs AB_BD so the host CPU or MMU can drive the address.

Following the Tpa state, the BIU enters the Td state to transfer data words. Each data transfer may be extended indefinitely by inserting Tw states. A slave acknowledges by asserting AB_ACK and transferring data in a Td state (cycle). If the slave can drive data at the rate of one word per clock (in a burst), it keeps AB_ACK asserted.

Following the final Td/Tw state, the BIU enters a Tr state to allow time to turn off or turn around bus transceivers.

A bus retry request is recognized in any Td/Tw state. The BIU will go to a Tr state and then rerun the transaction when it obtains a new Bus Grant. The whole transaction is retried, i.e., all words of a burst. Additionally, no other transaction will be attempted before the interrupted one is retried. The BIU retries indefinitely until either the transaction completes successfully, or a bus error is signaled.

Bus errors are recognized in Td/Tw states.

6.4.3 Physical Addressing Bus Transactions

Bus transactions in Physical Address Mode are shown in Figure 6-4 through Figure 6-7. MACSI device signals are defined in Section 8.

FIGURE 6-4. ABus Single Read: Physical Addressing—0 w/s, 1 w/s

TL/F/11705-9

6.0 Functional Description (Service Engine) (Continued)

Single Read

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tpa within the next three clocks.

Tpa: MACSI device drives AB_A and AB_AD with the address, asserts $\overline{AB_AS}$, drives AB_R/\overline{W} and $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ if another transaction is not required.

Td: MACSI device negates $\overline{AB_AS}$, asserts $\overline{AB_DEN}$, and samples $\overline{AB_ACK}$ and AB_ERR . Slave asserts $\overline{AB_ACK}$, drives AB_ERR , drives AB_AD (with data) when ready. The MACSI device samples a valid $\overline{AB_ACK}$, capturing the read data. Tw states may occur after Td.

Tr: MACSI device negates AB_R/\overline{W} , $\overline{AB_DEN}$, and $AB_SIZ[2:0]$, and releases AB_A and $\overline{AB_AS}$. Slave deasserts $\overline{AB_ACK}$ and AB_ERR , and releases AB_AD .

Single Write

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tpa within the next three clocks.

Tpa: MACSI device drives AB_A and AB_AD with the address, asserts $\overline{AB_AS}$, drives AB_R/\overline{W} and $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ if another transaction is not required.

Td: MACSI device negates $\overline{AB_AS}$, asserts $\overline{AB_DEN}$, drives AB_AD with the write data and starts sampling $\overline{AB_ACK}$ and AB_ERR . Slave captures AB_AD data, asserts $\overline{AB_ACK}$, and drives AB_ERR . Tw states may occur after Td if the slave deasserts $\overline{AB_ACK}$.

Tr: MACSI device negates AB_R/\overline{W} , $\overline{AB_DEN}$, and $AB_SIZ[2:0]$, and releases AB_A , AB_AD , and $\overline{AB_AS}$. Slave deasserts $\overline{AB_ACK}$ and AB_ERR and stops driving AB_AD with data.

6.0 Functional Description (Service Engine) (Continued)

FIGURE 6-6. ABUS Burst Read: Physical Addressing—16 Bytes, 1 w/s

TL/F/11705-11

Burst Read

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tpa within the next three clocks.

Tpa: MACSI device drives AB_A and AB_AD with the address, asserts $\overline{AB_AS}$, drives AB_R/\overline{W} and $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ if another transaction is not required.

Td: MACSI device asserts $\overline{AB_DEN}$, samples $\overline{AB_ACK}$ and $\overline{AB_ERR}$, and increments the address on AB_A . Slave asserts $\overline{AB_ACK}$, drives $\overline{AB_ERR}$, and drives AB_AD (with data) when ready. MACSI device samples a valid $\overline{AB_ACK}$ to capture the read data. Tw states may occur after Td. Td state is repeated four or eight times (according to the burst size). If $SIMR1.ASM = 0$, the MACSI device negates $\overline{AB_AS}$ in the last Td cycle. If $SIMR1.ASM = 1$, the MACSI device will negate $\overline{AB_AS}$ in the first Td cycle.

Tr: MACSI device negates AB_R/\overline{W} , $\overline{AB_DEN}$, and $AB_SIZ[2:0]$, and releases AB_A and $\overline{AB_AS}$. Slave deasserts $\overline{AB_ACK}$ and $\overline{AB_ERR}$ and releases AB_AD .

Burst Write

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tpa within the next three clocks.

Tpa: MACSI device drives AB_A and AB_AD with the address, asserts $\overline{AB_AS}$, drives AB_R/\overline{W} and $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ if another transaction is not required.

Td: MACSI device asserts $\overline{AB_DEN}$, drives AB_AD with the write data, samples $\overline{AB_ACK}$ and $\overline{AB_ERR}$, and increments the address on AB_A . Slave captures AB_AD data, asserts $\overline{AB_ACK}$, drives $\overline{AB_ERR}$. MACSI device samples a valid $\overline{AB_ACK}$. Tw states may occur after Td. Td state is repeated as required for the complete burst. If $SIMR1.ASM = 0$, the MACSI device negates $\overline{AB_AS}$ in the last Td cycle. If $SIMR1.ASM = 1$, the MACSI device will negate $\overline{AB_AS}$ in the first Td cycle.

Tr: MACSI device negates AB_R/\overline{W} , $\overline{AB_DEN}$, and $AB_SIZ[2:0]$, releases AB_A and $\overline{AB_AS}$, and stops driving AB_AD with data. Slave deasserts $\overline{AB_ACK}$ and $\overline{AB_ERR}$.

6.0 Functional Description (Service Engine) (Continued)

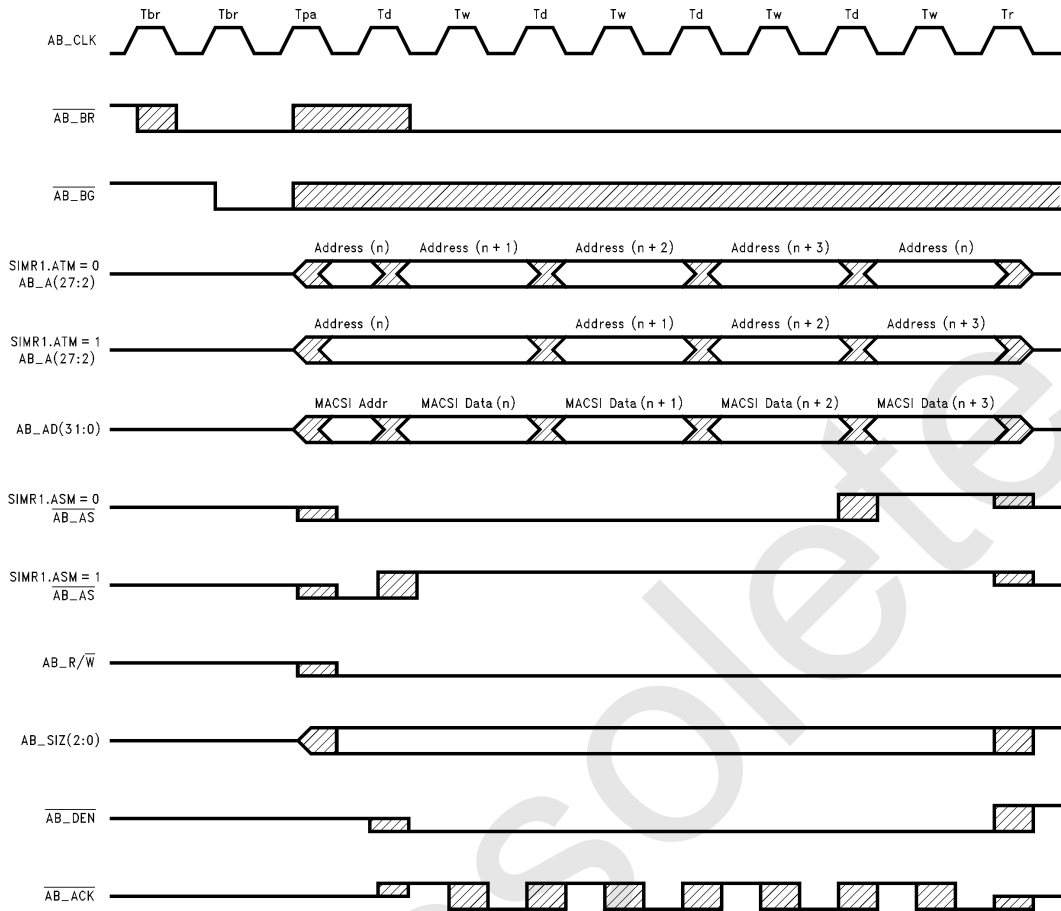

FIGURE 6-7. ABUS Burst Write: Physical Addressing—16 Bytes, 1 w/s

6.4.4 Virtual Addressing Bus Transactions

Single Read

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tva within the next three clocks, and then drives AB_A and AB_AD .

Tva: MACSI device drives AB_A and AB_AD with the virtual address for one clock, negates $\overline{AB_AS}$, asserts AB_R/\overline{W} , drives $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ if another transaction is not required.

Tmmu: Host MMU performs an address translation during this clock.

Tpa: Host MMU drives AB_AD with the translated (physical) address.

Td: MACSI device negates $\overline{AB_AS}$, asserts $\overline{AB_DEN}$, and samples $\overline{AB_ACK}$ and $\overline{AB_ERR}$. Slave asserts $\overline{AB_ACK}$, drives $\overline{AB_ERR}$, and drives AB_AD (with data) when ready. MACSI device samples a valid $\overline{AB_ACK}$, and captures the read data. Tw states may occur after Td.

Tr: MACSI device negates AB_R/\overline{W} , $\overline{AB_DEN}$, and $AB_SIZ[2:0]$, and releases AB_A and $\overline{AB_AS}$. Slave deasserts $\overline{AB_ACK}$ and $\overline{AB_ERR}$ and releases AB_AD .

Single Write

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tva within the next three clocks, and then drives AB_A and AB_AD .

Tva: MACSI device drives AB_A and AB_AD with the virtual address for one clock, negates $\overline{AB_AS}$, negates AB_R/\overline{W} , and drives $AB_SIZ[2:0]$.

6.0 Functional Description (Service Engine) (Continued)

Tmmu: Host MMU performs an address translation during this clock.

Tpa: Host MMU drives AB__AD with the address.

Td: MACSI device negates AB__AS, asserts AB__DEN, drives AB__AD with the write data and starts sampling AB__ACK and AB__ERR. Slave captures AB__AD data, asserts AB__ACK, and drives AB__ERR. MACSI device samples a valid AB__ACK. Tw states may occur after Td.

Tr: MACSI device negates AB__R/W, AB__DEN, and AB__SIZ[2:0], and releases AB__A, AB__AD, and AB__AS. Slave deasserts AB__ACK and AB__ERR and stops driving AB__AD with data.

Burst Read

Tbr: MACSI device asserts AB__BR to indicate it wishes to perform a transfer. Host asserts AB__BG. The MACSI device moves to Tva within the next three clocks, and then drives AB__A and AB__AD.

Tva: MACSI device drives AB__A and AB__AD with the virtual address for one clock, negates AB__AS, asserts AB__R/W, drives AB__SIZ[2:0], and negates AB__BR if another transaction is not required.

Tmmu: Host MMU performs an address translation during this clock.

Tpa: Host MMU drives AB__AD with the translated (physical) address.

Td: MACSI device asserts AB__DEN and samples AB__ACK and AB__ERR. Slave asserts AB__ACK, drives AB__ERR, and drives AB__AD (with data) when ready. MACSI device samples a valid AB__ACK, and captures the read data. Tw states may occur after Td. This state is repeated four or eight times (according to burst size). If SIMR1.ASM = 0 the MACSI device negates AB__AS in the last Td cycle. If SIMR1.ASM = 1, the MACSI device will negate AB__AS in the first Td cycle.

Tr: MACSI device negates AB__R/W, AB__DEN, and AB__SIZ[2:0], and releases AB__A and AB__AS. Slave deasserts AB__ACK and AB__ERR and releases AB__AD.

Burst Write

Tbr: MACSI device asserts AB__BR to indicate it wishes to perform a transfer. Host asserts AB__BG. The MACSI device moves to Tva within the next three clocks, and then drives AB__A and AB__AD.

Tva: MACSI device drives AB__A and AB__AD with the virtual address for one clock, negates AB__AS, negates AB__R/W, drives AB__SIZ[2:0].

Tmmu: Host MMU performs an address translation during this clock.

Tpa: Host MMU drives AB__AD with the address.

Td: MACSI device asserts AB__DEN, drives AB__AD with the write data, and starts sampling AB__ACK and AB__ERR. Slave captures AB__AD data, asserts AB__ACK and drives AB__ERR. MACSI device samples a valid AB__ACK. Tw states may occur after Td. Td is repeated as required for the complete burst. If SIMR1.ASM = 0, the MACSI device negates AB__AS in the last Td cycle. If SIMR1.ASM = 1, the MACSI device will negate AB__AS in the first Td cycle.

Tr: MACSI device negates AB__R/W, AB__DEN, and AB__SIZ[2:0], releases AB__A, AB__AD, and AB__AS, and stops driving AB__AD with data. Slave deasserts AB__ACK and AB__ERR.

6.5 ENHANCED ABUS MODE

When the enhanced ABUS mode is selected, several changes occur. The timing of AB__ACK is modified during read accesses. In this mode, read data is expected one cycle after the AB__ACK signal (see *Figure 6-8* and *Figure 6-11*). In addition, channel information is no longer supplied on the upper four bits of the Address/Data lines during the address cycle. Instead, the value of this nibble of address is supplied from a programmable register within the MACSI device (for a full description of these bits please see System Interface Mode Register1 (SIMR1)). Finally, the AB__DEN signal becomes an input in this enhanced mode. This signal, along with AB__ACK and AB__ERR, are used to encode a subset of the acknowledge, retry, and error functions supported on the SBus.

These enhancements make it easier to connect the MACSI device to the SBus as a bus master. However, a full FDDI adapter design requires the design of a slave interface from the SBus to the control bus of the MACSI device and the other FDDI components.

6.5.1 Enhanced ABUS Mode Bus Transactions

Bus transactions in the Enhanced ABUS Mode are shown in *Figure 6-8* through *Figure 6-11*. In the Enhanced ABUS mode, the Bus Request signal (AB__BR) will be deasserted after the bus is granted until the completion of the bus transaction. The only exception to this may occur when the MACSI device is attempting back-to-back burst reads. In this case AB__BR may be deasserted for as few as two cycles.

Single Read

Tbr: MACSI device asserts AB__BR to indicate it wishes to perform a transfer. Host asserts AB__BG. The MACSI device moves to Tma on the next cycle.

Tma: MACSI device drives AB__A and AB__AD with the master address, asserts AB__AS, drives AB__R/W and AB__SIZ[2:0], and negates AB__BR until the end of this transaction.

Tpa: The Physical address is asserted by the MMU.

Td: MACSI device negates AB__AS and samples AB__ACK, AB__ERR, and AB__DEN. Slave asserts AB__ACK, AB__ERR, and AB__DEN with the appropriate acknowledgment. The MACSI device samples a valid acknowledgment and moves to Tr. Tw states may occur after Td.

Tr: MACSI device negates AB__R/W, AB__DEN, and AB__SIZ[2:0], releases AB__A and AB__AS, and samples AB__AD. Slave drives AB__AD (with data), deasserts AB__ACK, AB__ERR, and AB__DEN, and releases AB__AD.

FIGURE 6-10. Enhanced ABUS Mode Burst Write Timing

Single Write

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tma in the next cycle.

Tma: MACSI device drives $\overline{AB_A}$ and $\overline{AB_AD}$ with the master address, asserts $\overline{AB_AS}$, drives $\overline{AB_R/W}$ and $\overline{AB_SIZ}[2:0]$, and negates $\overline{AB_BR}$ until the end of this transaction.

Tpa: The Physical address is asserted by the MMU.

Td: MACSI device negates $\overline{AB_AS}$, drives $\overline{AB_AD}$ with the write data and starts sampling $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$. Slave captures $\overline{AB_AD}$ data, and acknowledges with $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$. Tw states may occur after Td if the slave does not acknowledge.

Tr: MACSI device negates $\overline{AB_R/W}$, $\overline{AB_SIZ}[2:0]$, releases $\overline{AB_A}$, $\overline{AB_AD}$, and $\overline{AB_AS}$, and stops driving $\overline{AB_AD}$ with data. Slave deasserts $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$.

6.0 Functional Description (Service Engine) (Continued)

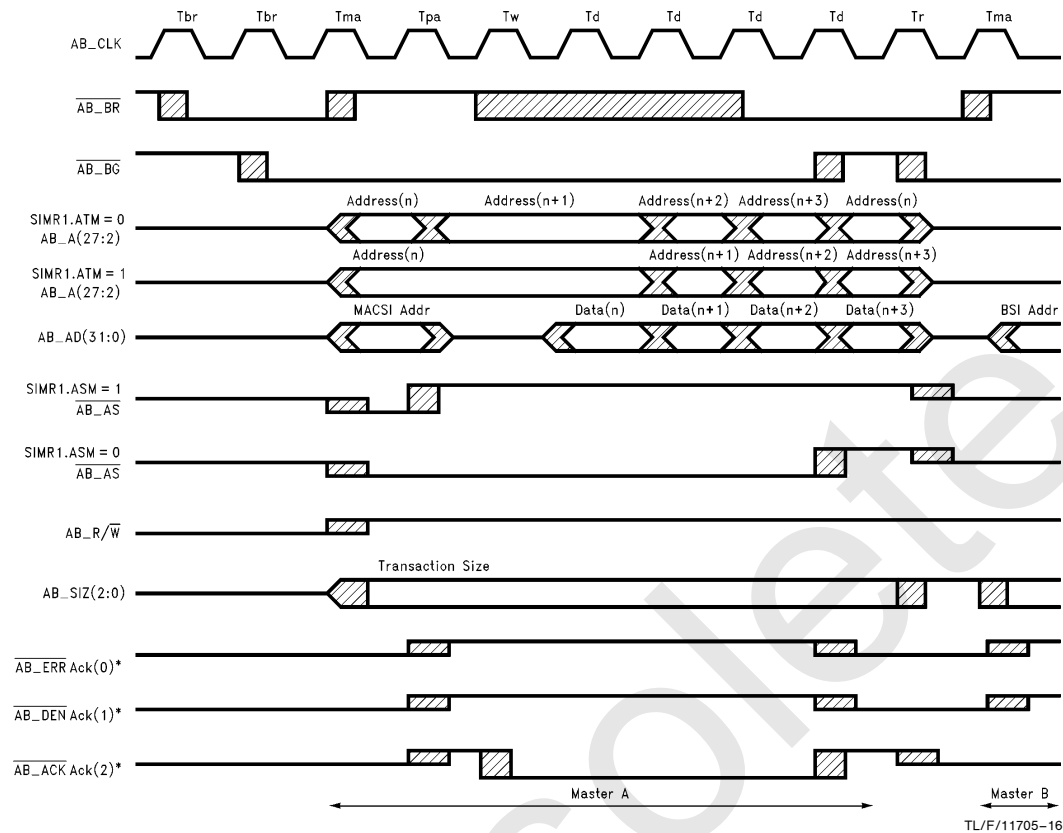

FIGURE 6-11. Enhanced ABus Mode Back-to-Back Read Timing

TL/F/11705-16

Burst Read

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tma in the next cycle. This cycle may be skipped if $\overline{AB_BR}$ was asserted during the previous access. This allows for back-to-back burst reads.

Tma: MACSI device drives AB_A and AB_AD with the master address, asserts $\overline{AB_AS}$, drives AB_R/\overline{W} and $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ for at least two cycles.

Tpa: The Physical Address is asserted by the MMU.

Td: MACSI device samples $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$, and increments the address on AB_A . Slave acknowledges using $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$. MACSI device samples a valid $\overline{AB_ACK}$ and latches data in the following cycle. T_w states may occur after T_d . T_d state is repeated four or eight times (according to the burst size). If $SIMR1.ASM = 0$, the MACSI device negates $\overline{AB_AS}$ in the last T_d cycle. If $SIMR1.ASM = 1$, the MACSI device negates $\overline{AB_AS}$ in the first T_d cycle.

Tr: MACSI device negates AB_R/\overline{W} and $AB_SIZ[2:0]$ and releases AB_A and $\overline{AB_AS}$. Slave drives AB_AD (with data), deasserts $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$. If another request is pending ($\overline{AB_BR}$ asserted) and the Bus is

regranted in this cycle, the MACSI device will proceed directly to the Tma state of the next burst. The normal Tbr state is skipped allowing back-to-back burst reads.

Burst Write

Tbr: MACSI device asserts $\overline{AB_BR}$ to indicate it wishes to perform a transfer. Host asserts $\overline{AB_BG}$. The MACSI device moves to Tma in the next cycle.

Tma: MACSI device drives AB_A and AB_AD with the master address, asserts $\overline{AB_AS}$, drives AB_R/\overline{W} and $AB_SIZ[2:0]$, and negates $\overline{AB_BR}$ until this transaction is completed.

Tpa: The Physical Address is asserted by the MMU.

Td: MACSI device drives AB_AD with the write data, samples $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$, and increments the address on AB_A . Slave captures AB_AD data and acknowledges using $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$. MACSI device samples a valid acknowledge. T_w states may occur after T_d . T_d state is repeated as required for the complete burst. If $SIMR1.ASM = 0$, the MACSI device negates $\overline{AB_AS}$ in the last T_d cycle. If $SIMR1.ASM = 1$, the MACSI device negates $\overline{AB_AS}$ in the first T_d cycle.

Tr: MACSI device negates AB_R/\overline{W} , $AB_SIZ[2:0]$, releases AB_A and $\overline{AB_AS}$, and stops driving AB_AD with data. Slave deasserts $\overline{AB_ACK}$, $\overline{AB_ERR}$, and $\overline{AB_DEN}$.

7.0 Control Information

7.1 OVERVIEW

The Control Information includes Operation, Event, Status and Parameter Registers that are used to manage and operate the MACSI Device. A controller on the external Control Bus gains access to read and write these parameters via the Control Bus Interface.

The MACSI device combines the functions of the original DP83261 BMAC device and the DP83265 BSI device with many enhanced capabilities. The MACSI device has additional Control Bus address lines compared to the BMAC and BSI devices (CBA(8:0)). When the most significant address bit (CBA8) is zero, the internal BMAC register block is se-

lected. When CBA8 is 1, the internal BSI register block is selected. The actual addresses within the MACSI device are defined in Table 7-1 and Table 7-2.

All registers and control bits within the BSI register block of the MACSI device have the same relative addresses and functions as they do in the BSI device. All registers and control bits within the BMAC register block of the MACSI device have the same relative addresses and functions as they do in the BMAC device. The only exceptions to this are shown in the detailed register descriptions following the memory map table. There are two registers which have new features unique to the MACSI device or functions which are slightly modified from the original BMAC or BSI device. These are MCMR0 and MCMR2.

TABLE 7-1. MACSI Memory Map (BMAC Registers)

The MAC Control Information Address Space is divided into 4 groups as shown in Table 7-3. An information summary is given for each group followed by a detailed description of all registers.

- MAC Operation Registers (Table 7-4)
- MAC Event Registers (Table 7-5)
- MAC Parameters (Table 7-6)
- MAC Counters/Timers (Table 7-7)

The System Interface Operation registers are accessed directly via the Control Bus. Limit RAM Registers are accessed indirectly via the Control Bus using the Limit RAM Data and Limit RAM Address Registers. The Pointer RAM Registers are accessed indirectly via the Control Bus and

ABus using the Pointer RAM Address and Control Register, the Mailbox Address Register, and a mailbox location in ABus memory. Descriptors are fetched (or written) by the MACSI device across the ABus.

- System Interface Registers (Table 7-8)

7.2 CONVENTIONS

When referring to multi-byte fields, byte 0 is always the most significant byte. When referring to bits within a byte, bit (7) is the most significant bit and bit (0) is the least significant bit. When referring to the contents of a byte, the most significant bit is always referred to first. When referring to a bit within a byte the notation `register_name.bit_name` is used. For example, `MCMR0.RUN` references the RUN bit in MAC Mode Register 0.

7.0 Control Information (Continued)

TABLE 7-3. MAC Control Information Address Space

Address Range	Description	Read Conditions	Write Conditions
000–007	Operation Registers	Always (Note 2)	Always (Note 2)
008–02F	Event Registers	Always (Note 2)	Always (cond) (Note 2)
030–03F	Reserved	N/A (Note 4)	N/A (Note 4)
040–07F	MAC Parameters	Stop Mode (Notes 1, 3)	Stop Mode (Notes 1, 3)
080–0BF	Counters/Timers	Always	Stop Mode (Note 1)
0C0–0FF	Reserved	N/A (Note 4)	N/A (Note 4)

Note 1: An attempt to access a currently inaccessible MAC Control location because of the current mode or because it is a reserved address space will cause a command error (bit CCE of the Exception Status Register is set to One).

Note 2: Read and write accesses to reserved locations within the Operation and Event Address ranges of the MAC Control Information Space cause a command error (bit CCE of the Exception Status Register is set to One).

Note 3: The MAC Parameter RAM is also accessible when conditions a, b and c are true. Otherwise accesses will cause a command error (bit CCE of the Exception Status Register is set to One) and the access will not be performed.

a) The MAC Transmitter is in state T0 or T1 or T3;

b) Option.ITC = 1 and Option.IRR = 1

c) Function.BCN = 0 and Function.CLM = 0

Note 4: Reserved bits in registers are always read as 0 and are not writable.

TABLE 7-4. MAC Operation Registers

030-03F	Reserved	RES	RES	RES	RES	RES	RES	RES	RES	N/A	N/A

Note 1: Attempts to access reserved locations within the MAC Event Registers will result in Command Rejects (ESR.CCE set to ONE).

Note 2: Bits in the conditional write registers are only written when the corresponding bit in the Compare Register is equal to the bit to be overwritten.

Note 3: On Master Reset all Event Registers are reset to Zero.

7.3 ACCESS RULES

For the Ring Engine (MAC), all Control Interface accesses are checked against the current operational mode to determine if the register is currently accessible. If not currently accessible, the Control Bus Interface access is rejected (and reported in an Event Register). This means that the Control Bus Interface completes all accesses in a deterministic amount of time. Certain Status and Parameter registers are not accessible while in Run mode because the Ring Engine might access those locations. The Exception

Status Register can be checked to verify that the operation terminated normally.

The Service Engine Registers are always accessible.

7.3.1 MAC Parameter RAM

The MAC parameter RAM is accessible in Stop mode and in RUN mode while: the MAC Transmitter is in states T0, T1 or T3; Option.ITC and Option.IRR are set; and Function.BCN and Function.CLM are not set. Otherwise a command reject is given (ESR.CCE) and the Parameter RAM will not be read or written.

0BA	TKCT2	TKCT(15–8)
0BB	TKCT3	TKCT(7–0)
0BC	RLCT0	Zero(31–24)
0BD	RLCT1	Null(7–4), RLCT(19–16)
0BE	RLCT2	RLCT(15–8)
0BF	RLCT3	RLCT(7–0)

Note 1: Null(7–4) indicates that these bits are forced to zero on reads, and are ignored on writes.

Note 2: The value obtained on reads from reserved locations is not specified.

Note 3: On Master Reset, the event counters are not cleared.

The event counters are 20-bit counters and are read through three control accesses. In order to guarantee a consistent snapshot, whenever byte 3 of an event counter is read, byte 1 and byte 2 of the counters are loaded into a holding register. Byte 1 and byte 2 may then be read from the holding register. A single holding register is shared by all of the counters but (for convenience) is accessible at several places within the address space. Consistent readings across counters can be accomplished using the Counter Increment Latch Register (CILR).

The event counters are not reset as a result of a Master Reset. This may be done by either reading the counters out and keeping track relative to the initial value read, or by writing a value to all of the counters in stop mode. The counters may be written in any order. With some exceptions, interrupts are available when the counters increment or wraparound.

Note: Bits in the conditional write registers are only written when the corresponding bit in the System Interface Compare Register is equal to the bit to be overwritten.

7.0 Control Information (Continued)

Control Registers

The Control Registers are used to configure and control the operation of the MACSI device.

The Control Registers include the following registers:

- **MAC Mode Registers (MCMR2-0)** establish the major operating parameters for the MAC portion of the MACSI device.
- **Option Register (Option)** selects major configuration options for the MAC portion of the device.
- **Function Register (Function)** initiates major MAC level functions.
- **MAC Revision (MCRev)** this register contains the silicon revision code for the MAC state machines of this device.
- **System Interface Mode Registers (SIMR1-0)** establishes major operating parameters for the System Interface.
- **Pointer RAM Control and Address Register (PCAR)** is used to program the parameters for the PTOp (Pointer RAM Operation) service function.
- **Mailbox Address Register (MBAR)** is used to program the memory address of the mailbox used in the data transfer of the PTOp service function.
- **Limit Address Register (LAR)** is used to program the parameters and data used in the LMOP (Limit RAM Operation) service function.
- **Limit Data Register (LDR)** is used to program the data used in the LMOP service function.

- **Request Channel 0 Configuration Registers (R0CR1-0)** are used to program the operational parameters for Request Channel 0.
- **Request Channel 1 Configuration Registers (R1CR1-0)** are used to program the operational parameters for Request Channel 1.
- **Request Channel 0 Expected Frame Status Register (R0EFSR)** defines the expected frame status for frames being confirmed on Request Channel 0.
- **Request Channel 1 Expected Frame Status Register (R1EFSR)** defines the expected frame status for frames being confirmed on Request Channel 1.
- **Indicate Threshold Register (ITR)** is used to specify a maximum number of frames that can be copied onto an Indicate Channel before a breakpoint is generated.
- **Indicate Mode Configuration Register (IMCR)** specifies how the incoming frames are sorted onto Indicate Channels, enables frame filtering, and enables breakpoints on various burst boundaries.
- **Indicate Copy Configuration Register (ICCR)** is used to program the copy criteria for each of the Indicate Channels.
- **Indicate Header Length Register (IHLR)** defines the length of the frame header for use with the Header/Info Sort Mode.

Event Registers

The Event Registers record the occurrence of events or series of events. Events are recorded and contribute to generating Interrupt signals. There is a two-level hierarchy in generating this signal, as shown in *Figure 7-1*.

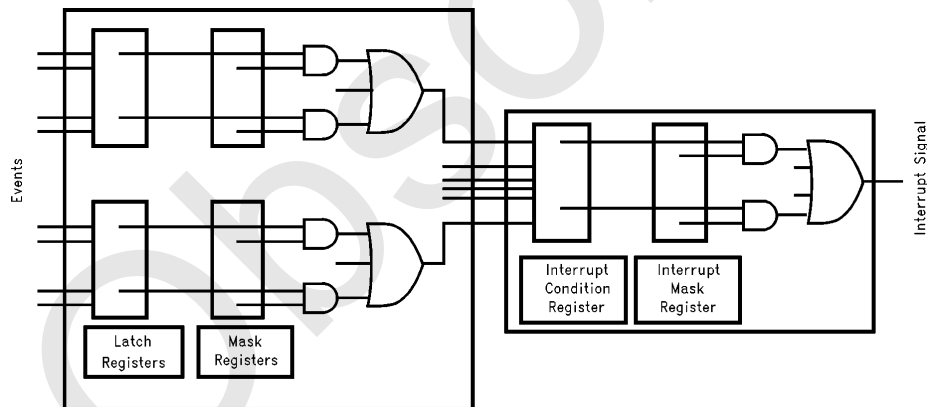

FIGURE 7-1. Event Registers Hierarchy

TL/F/11705-17

7.0 Control Information (Continued)

The MACSI device has two interrupts signals. One provides interrupts on those events generated by the MAC state machines (INT0) and the other provides interrupts on those events generated by the System Interface state machines (INT1). This partition maintains hardware and software compatibility with earlier designs based on the BMAC and BSI devices.

At the first level of the hierarchy, events are recorded as bits in the Attention Registers (e.g., No Space Attention Register). Each Attention Register has a corresponding Notify Register (e.g., No Space Notify Register). When a bit in the Attention Register is set to One and its corresponding bit in the Notify Register is also set to One, the corresponding bit in the Master Attention Register will be set to one.

At the second level of the hierarchy, if a bit in the Master Attention Register is set to One and the corresponding bit in the Master Notify Register is set to One, the Interrupt signal is asserted.

To ensure that events are not missed when updating the attention registers, all attention registers are conditional write registers. Bits in Conditional Write Registers (e.g., No Space Attention Register) are only written when the corresponding bits in the Compare Register are equal to the bits to be overwritten. Read operations for conditional write registers automatically cause the Compare Register to be loaded with the contents of the conditional write register being accessed. The MACSI device contains two compare registers. One is used for Ring Engine Event Registers (MCCMP) and the other is used for System Interface Event Registers (SICMP).

Events are recorded in Attention Registers and contribute to the Interrupt when the bit in the corresponding Notify Register is set (see *Figure 7-1*). Bits in the Master Attention Register (MAR) are not cleared directly. They are cleared by clearing the lower level attention and/or notify register.

The Event Registers include the following registers:

- Ring Engine Event Registers (INT0):
 - MAC Compare Register (MCCMP)
 - Current Receiver Status Register (CRS0)
 - Current Transmitter Status Register (CTS0)
 - Ring Event Latch Registers (REL0–1)
 - Ring Event Mask Registers (REMR0–1)
 - Token and Timer Event Latch Register (TELR0)
 - Token and Timer Event Mask Register (TEMR0)
 - Counter Increment Latch Register (CILR)
 - Counter Increment Mask Register (CIMR)
 - Counter Overflow Latch Register (COLR)
 - Counter Overflow Mask Register (COMR)
 - Internal Event Latch Register (IELR)
 - Exception Status Register (ESR)
 - Exception Mask Register (EMR)
 - Interrupt Condition Register (ICR)
 - Interrupt Mask Register (IMR)
- Service Engine Event Registers (INT1)
 - Master Attention Register (MAR)
 - Master Notify Register (MNR)
 - State Attention Register (STAR)

- State Notify Register (STNR)
- Service Attention Register (SAR)
- Service Notify Register (SNR)
- No Space Attention Register (NSAR)
- No Space Notify Register (NSNR)
- Request Attention Register (RAR)
- Request Notify Register (RNR)
- Indicate Attention Register (IAR)
- Indicate Notify Register (INR)
- System Interface Compare Register (SICMP)

Servicing Interrupts

In the process of servicing an interrupt, the Host may use one or both levels of condition masks to disable new interrupts while one is being serviced. Soon after the Management Entity has processed the interrupt to some extent, it is ready to re-arm the interrupt in order to be notified of the next condition.

The Interrupt Control Register always contains the merged output of the masked Condition Registers as shown in *Figure 7-1*. It is only possible to remove a condition by setting the corresponding Condition Latch Register bit to Zero. By storing the events on-chip and having the ability to selectively set bits to Zero, the need for the software to maintain a copy of the Event Registers is eliminated.

To prevent the overwriting and consequent missing of events, an interlock mechanism is used. In the period between the Read of a Condition Latch Register and the corresponding Write to reset the condition, additional events can occur.

In order to prevent software from overwriting bits which have changed since the last read and losing interrupt events, a conditional write mechanism is employed. Only bits that have not changed since the last read can be written to a new value.

Whenever a Condition Latch Register is read, its contents are stored in the Compare Register. There is one Compare Register for the Ring Engine Event Registers and one Compare Register for the Service Engine Event Registers. Each bit of the Compare Register is compared with the current contents of the Register that is to be written. Writing a bit with a new value to a Condition Register is only possible when the corresponding bit in the Compare Register matches the bit in the Condition Register. For any bit that has not changed, the new value of the bit is written into the Register. For any bit that has changed, the writing of the bit is inhibited. The fact that an attempt was made to change a modified bit in the Register is latched in the Condition Write Inhibit bit in the Exception Status Register (ESR.CWI) for Ring Engine Registers and in the State Attention Register (STAR.CWI) for Service Engine Registers.

In the MACSI device, two Compare Registers are shared by all of the Condition Latch Registers (In the PLAYER+ device, there is a Compare Register for every Event Register). For the cases where more than one register must be read before writing a new value, the software may write the appropriate Compare Register with the most recently read value before writing the register again. Alternatively, the Event Register may be read again before being written.

7.0 Control Information (Continued)

7.4 RING ENGINE OPERATION REGISTERS

The Operation Registers are used to control the operation of the Ring Engine. The Operation Registers include the following registers

- MAC Mode Register (MCMR0, MCMR2)
- Option Register (Option)
- Function Register (Function)
- MAC Revision Register (MCRev)

MAC Mode Register 0 (MCMR0)

The Mode Register contains the current mode of the Ring Engine.

Access Rules

Address	Read	Write
000h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
DIAG	ILB	RES	RES	PIP	MRP	CBP	RUN

Bit	Symbol	Description
D7	DIAG	<p>Diagnose Mode: Enables access to all Ring Engine registers. When set, interoperability is not guaranteed. This bit should only be set when the Ring Engine is not inserted in a ring.</p> <p>Design Note: In diagnose mode, should an internal error occur the Current Receive and Transmit Status Registers are frozen with the error state until the internal state machine error condition is cleared (IELR.RSMERR and/or IELR.TSMERR).</p>
D6	ILB	<p>Internal Loopback: Enables the internal loopback that connects PRP, PRC, and PRD7–0 to PIP, PIC, and PID7–0 respectively. When enabled, the PHY Indicate Interface is ignored.</p> <p>Since the Ring Engine Transmitter and Receiver work as independent processes, a ring can be made operational in this mode, albeit consisting only of a single MAC. With an operational ring many diagnostic tests can be performed to test out MAC level and system level diagnostics including: the Beacon Process, the Claim Process, Ring Engine frame generation, token timers, event counters, transmission options, test of event detection capabilities, test of addressing modes, test of state machine sequencing options, etc. In addition, a large portion of the system interface logic can be tested, such as full duplex transmission to self within the limits of the system interface performance constraints, status handling and generation, etc.</p> <p>The same system tests can also be performed at different levels of loopback including through the various paths within a station, through the Configuration Switch of the PLAYER+ device, and through the Clock Recovery Module of the PLAYER+ device. System level tests can also be performed through the ring during normal operation.</p>
D5–D4	RES	Reserved
D3	PIP	<p>PHY Indicate Parity: Enables Odd Parity checking on the PHY Indicate Data pins (PID7–0). Parity errors are treated as code violations and cause the byte in error to be replaced with Idle symbols. When repeating, Parity is passed transparently from PIP to PRP. Odd Parity is generated for all internally generated fields. Odd Parity is always generated on the PHY Request Data pins (PRD7–0).</p>
D2	MRP	<p>MAC Request Parity: Enables Odd Parity checking on the MAC Request Data pins (MRD7–0). A parity error causes the transmission to be aborted. Odd parity is always generated on MIP.</p>
D1	CBP	<p>Control Bus Parity: Enables Odd Parity checking on the Control Bus Data pins (CBD7–0) during write operations. This applies to both the System Interface block and the Ring Engine (MAC) block. Parity errors detected while writing to a MAC register (CBA8 = 0) are reported in the CPE bit of the Exception Status Register (ESR 012Ch). Parity errors detected while writing to the System Interface block (CBA8 = 1) are reported in the CPE bit of the State Attention Register (STAR 106h). In either case, the write operation is inhibited.</p> <p>Parity is always generated on CBD7–0 during read accesses.</p>
D0	RUN	<p>RUN/Stop:</p> <p>0: Stop Mode All state machines return to and remain in their zero state. All counters and timers are disabled. The Ring Engine transmits Idle symbols.</p> <p>1: Run Mode. Enables operation as a MAC entity. The Ring Engine (MAC) must be in Run Mode to achieve an operational Ring.</p>

7.0 Control Information (Continued)

Option Register (Option)

The Ring Engine supports several options. These options are typically static during operation but may be altered during operation. This register is initialized to Zero after a master reset.

Access Rules

Address	Read	Write
001h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
ITC	EMIND	IFCS	IRPT	IRR	ITR	ELA	ESA

Bit	Symbol	Description
D7	ITC	<p>Inhibit Token Capture: When enabled, the Ring Engine is prohibited from transmitting any (more) frames. This option prohibits entry to the Transmit Void and Data states from the Idle state, and causes exit from the Data state after the current frame has been transmitted.</p> <p>When enabled, it is still possible to perform Immediate transmissions from the transmitter Claim and Beacon states, but not from the Data state.</p> <p>This option can be used to temporarily block normal data service. It can also be used in conjunction with the Inhibit Recovery Required option to permit access via the Control Interface to the MAC Parameter RAM during MAC operation.</p>
D6	EMIND	<p>External Matching Indicators: Enables the setting of the transmitted A Indicator as an S symbol when the EA pin is set. This bit also enables the setting of the transmitted C Indicator as an S symbol when the internal VCOPY signal is asserted by the System Interface and the A Indicator is set as a result of an external match (i.e., the User asserts the EA pin). The Copied/Not Copied Frame Counters also increment as a result of external comparisons when this option is enabled.</p>
D5	IFCS	<p>Implementer FCS: Enables use of the standard CRC as the FCS on Implementer frames (FC.FF = 10). When enabled, Implementer frames are treated like all other frames. When Implementer frames are received with bad FCS and Er = R, the E Indicator is transmitted as S and EICT is incremented.</p> <p>On Implementer frames, the Standard does not mandate the setting of the E Indicator on the result of the FCS check. This allows Implementers to use alternate Frame Check Sequences aside from the standard 32-bit CRC. Implementers may also choose not to use any FCS in applications such as packet voice.</p> <p>If other stations in the ring are using Implementer frames with a non-standard FCS, this option may cause an interoperability problem.</p>
D4	IRPT	<p>Inhibit Repeat: When enabled,</p> <ol style="list-style-type: none"> the Ring Engine cannot enter the Transmitter Repeat and Issue__Token states. This causes all received PDUs to be stripped and prevents tokens from being issued. Void frames are not transmitted during a service opportunity. Idle to Repeat transition is inhibited and all received tokens and MAC frames except Lower__Claim and My__Beacon frames are ignored (Lower__Claim and My__Beacon frames may be ignored by setting Option.IRR). <p>When the ring is operational, enabling this option causes the Reset actions to occur upon the completion of the service opportunity, if any. When the ring is not operational, Immediate Requests are serviced and continue to completion.</p> <p>The Inhibit Repeat option can be used to scrub the ring for a period longer than the Ring Latency. The option is also useful in non-FDDI applications to allow full duplex communication.</p>

7.0 Control Information (Continued)

Bit	Symbol	Description
D3	IRR	<p>Inhibit Recovery Required: When bit IRR is set to One, the Ring Engine does not take the transitions into the Claim state (T4). This option inhibits all the recovery required transitions as defined in the FDDI MAC Standard. This bit does not inhibit entry to the Tx_Claim state on a Claim Request generated at the MAC Request Interface via the Function Register.</p> <p>This option can be used to guarantee that implementation specific Beacon frames will be transmitted from the Tx_Beacon state. It is also useful in systems where Local Address Administration is used, to prohibit stations with the Null Address (or any address) from Claiming. The option could also be used to enable the use of the Ring Engine in non-FDDI full duplex applications (in conjunction with the Inhibit Repeat option) to disable the recovery timers.</p>
D2	ITR	<p>Inhibit Token Release: When bit ITR is set to One, the station will not issue a token after winning the Claim Process. The station remains in the Tx_Claim state while the station's Claim frames are returning to the station and it has won the Claim process. At this point the station is in control of the ring as long as no Higher_Claim or Beacon frames are received.</p> <p>While in control of the ring, the station may transmit special Claim or Management frames for a variety of implementation specific purposes. For example, the station might send out a Claim frame with a unique identifier to make sure that another station with its address and TREQ is not also Claiming.</p>
D1	ELA	<p>Enable Long Addressing: Enables the setting of A_Flag on matches of received Long Destination Addresses with MLA or any of the configured Group Addresses. Enables the setting of M_Flag and stripping on matches of received Long Source Address with MLA.</p> <p>Permits transmission of frames with Long Addresses. Frames with long addresses can be transmitted when long addressing is not enabled if the SA transparency option is selected.</p> <p>Claim and Beacon frames are sent with the Long Address if ELA is One. If ELA is Zero and ESA is One, Claim and Beacon frames are sent with the Short Address.</p> <p>When both ESA and ELA are Zero, the ring is effectively interrupted at this station. The token capture process and Error Recovery logic are suspended and no frames are repeated. Immediate requests are serviced if the SA Transparency option is selected.</p>
D0	ESA	<p>Enable Short Addressing: Enables the setting of A_Flag on matches of received Short Destination Addresses with MSA or any of the configured Group Addresses. Enables the setting of M_Flag and stripping on matches of received Short Source Addresses with MSA.</p> <p>Permits transmission of frames with Short Addresses. Frames with Short Addresses can be transmitted when Short Addressing is not enabled if the SA Transparency option is selected.</p> <p>Void frames are sent with the Short Address if ESA is set to One. If ESA is Zero and ELA is One, Void frames are sent with the Long Address.</p> <p>When both the ESA and ELA bits are Zero, the ring is effectively interrupted at this station. The token capture process and Error Recovery logic are suspended and no frames are repeated. Immediate requests are serviced if the SA Transparency option is selected.</p>

7.0 Control Information (Continued)

Function Register (Function)

The Ring Engine performs the MAC Reset, Claim Request, and Beacon Request using the Function Register. The Register is initialized to Zero after a master reset. A function is performed by setting the appropriate bit to One. When the function is complete, the bit is cleared by the Ring Engine.

Access Rules

Address	Read	Write
002h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
RES	RES	RES	CLM	BCN	MCRST	RES	MARST

Bit	Symbol	Description
D7–D5	RES	Reserved
D4	CLM	<p>Claim Request: Produces the functions equivalent to an SM__CONTROL.request (Claim) and causes entry to the Tx__Claim State. The Ring Engine Transmitter is forced to enter the Tx__Claim State unless the Transmitter is in the Tx__Beacon State or bit BCN is set to One. Claim frames are then transmitted until the Claim process completes. The Claim process will not complete if Option.ITR = 1.</p> <p>A Claim Request is honored immediately from any state except the Beacon state. It is honored in the Beacon state when a My__Beacon returns. Claim requests are honored even when Option.IRR = 1.</p> <p>Claim frames are generated by the Ring Engine unless an Immediate Claim Request is available at the MAC Request Interface. Even with an Immediate Claim Request at the Interface, the Ring Engine transmits at least one Claim frame before the Claim frames from the MAC Request Interface are transmitted.</p> <p>If an external Claim frame is to be transmitted, the Claim frame should first be set up, then the request should be given to the MAC Request Interface before the CLM bit is set to One.</p> <p>The CLM bit is reset upon entry to the Claim or Beacon state.</p>
D3	BCN	<p>Beacon Request: Produces the functions of an SM__CONTROL.request (Beacon) as required by the FDDI MAC Standard. The Ring Engine Transmitter is forced to enter the Tx__Beacon State. Beacon frames are then transmitted until the Tx__Beacon Process completes. The Beacon Process will not complete if Option.IRR = 1.</p> <p>Beacon frames are generated by the Ring Engine unless an Immediate Beacon Request is present at the MAC Request Interface and a frame is ready to be transmitted. Even with an External Immediate Beacon Request the Ring Engine transmits at least one Beacon frame before the Beacon frames from the MAC Request Interface are transmitted.</p> <p>If an external Beacon frame is to be transmitted, the Beacon frame should first be set up via the System Interface and then bit BCN should be set to One.</p> <p>Setting this bit also sets bit D2 (MCRST). The BCN bit is cleared on entry to the Beacon state. If the User programs both D3 (BCN) and D4 (CLM) simultaneously, bit D3 (BCN) takes precedence.</p>
D2	MCRST	<p>MAC Reset: Forces the Receiver to state R0 (Listen) and the Transmitter to state T0 (Idle).</p> <p>TNEG (Registers 098–09B) is not loaded with TMAX (this operation can be performed as part of the MAC Reset Request actions by writing to TNEG Timers before the MAC Reset is initiated).</p> <p>MCRST takes precedence over bits D3 (BCN) and D4 (CLM), but does not clear these bits.</p> <p>A MAC Reset that occurs while a frame is being transmitted will cause the frame to be aborted. Frames without the Frame Status are not transmitted by the Ring Engine. Whenever the byte with the Ending Delimiter is transmitted, valid frame status is transmitted as well. If a MAC Reset occurs during the byte where the Ending Delimiter and E Indicator should be transmitted, it will not be transmitted. If a MAC Reset occurs on the cycle where the A and C Indicators are transmitted, they will still be transmitted.</p>
D1	RES	Reserved
D0	MARST	<p>Master Reset: A Master Reset is functionally equivalent to a hardware reset of the Ring Engine (MAC). A Master Reset sets all Ring Engine state machines and registers to default values.</p> <p>Master Reset causes the MCRST bit to be set. It also clears the Mode, Option, Event and Mask Registers. The Timers are set to their defaults. The Counters are not cleared.</p> <p>When the Master Reset function is complete, bit D0 (MARST) is set to Zero. At this time, all bits in the Function Register should be Zero.</p>

7.0 Control Information (Continued)

MAC Mode Register 2 (MCMR2)

The Mode Register 2 (MCMR2) is used to program major operating parameters for the MAC portion of the MACSI device. This register should be programmed only at power-on, or after a software or hardware Master Reset.

This register is cleared upon reset.

Access Rules

Address	Read	Write
005h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
RES	RES	RES	AFIE	LLC MCE	SMT MCE	RES	BOSEL

Bit	Symbol	Description
D5–D7	RES	Reserved
D4	AFIE	AFLAG Inhibit Enable: For MACSI Revision D or later, this bit enables the recognition of the $\overline{\text{AFINHIB}}$ input pin. When AFIE equals zero, the MACSI device will ignore the $\overline{\text{AFINHIB}}$ input. When AFIE equals one, the MACSI will block the internal address recognition flag (AFLAG) between the MAC and System Interface whenever the User asserts the $\overline{\text{AFINHIB}}$ pin. For MACSI Revision prior to D, this is a Reserved bit.
D3	LLC MCE	LLC Multicast Enable (LLC MCE): When this bit is set, the MACSI device will attempt to copy any LLC frame (as determined by the FC field) which also has the Individual/Group address bit set (i.e., is using a multicast address). The MAC block will not set the A or C indicators and the copied/not copied counters will not increment.
D2	SMT MCE	SMT/MAC Multicast Enable (SMT MCE): When this bit is set, the MACSI device will attempt to copy any SMT or MAC frame (as determined by the FC field) which also has the Individual/Group address bit set (i.e., is using a multicast address). The MAC block will not set the A or C indicators and the copied/not copied counters will not increment.
D1	RES	Reserved
D0	BOSEL	Bridge Option Select (BOSEL): This bit controls the interconnect of the STRIP and SAT signals from the System Interface block to the MAC block. When BOSEL = 0, the SAT output from the System Interface is connected to SAT input of the MAC. When BOSEL = 1, the STRIP output of the System Interface is connected to the SAT input of the MAC.

MAC Revision Register (MCRev)

The MAC Revision Register (MCRev) contains the revision number of the Ring Engine.

Current Transmitter Status Register (CTS0)

The Current Transmitter Status Register (CTS0) records the status of the Transmitter state machine. It is continuously updated. It remains stable when accessed.

When in Diagnose Mode, this register is frozen on an internal error until the internal error event is cleared by resetting the TSMERR bit in the Internal Event Latch Register.

7.0 Control Information (Continued)

Ring Event Latch Register 0 (RELRO)

The Ring Event Latch Register 0 (RELRO) captures conditions that occur on the Ring including the receipt of Beacon and Claim frames, transitions in the Ring Operational flag, and the receipt of duplicate addresses. Each bit may be masked via the Ring Event Mask Register 0 (REMR0).

Access Rules

Address	Read	Write
010h	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
RES	DUPADD	PINV	OTRMAC	CLMR	BCNR	RNOP	ROP

Bit	Symbol	Description
D7	RES	Reserved
D6	DUPADD	Duplicate Address Received: Indicates that a valid individual frame addressed to this station was received with the A Indicator set. This could be caused by either a MAC using the same address (duplicate address) or a strip error at the Source (the frame was received twice).
D5	PINV	PHY_Invalid Received: Indicates that a PHY_Invalid was received. This could be the result of a PLAYER+ device Reset operation. PHY_Invalid causes the MAC Receiver to enter state R0 (Listen).
D4	OTRMAC	Other MAC Frame Received: Indicates that a MAC frame other than a Beacon or Claim frame was received. When set, restricted requests are not serviced.
D3	CLMR	Claim Frame Received: Indicates that a valid Claim frame was received. When set, restricted requests are not serviced. The type of Claim frame received is given in Register RELR1.
D2	BCNR	Beacon Frame Received: Indicates that a valid Beacon frame was received. When set, restricted and synchronous requests are not serviced. The type of Beacon frame received is given in Register RELR1.
D1	RNOP	Ring Non-Operational Set: Is set when the Local Ring Operational flag transitions from 1 to 0.
D0	ROP	Ring Operational Set: Is set when the Local Ring Operational flag transitions from 0 to 1.

7.0 Control Information (Continued)

Ring Event Mask Register 0 (REMR0)

The Ring Event Mask Register 0 (REMR0) is used to mask bits in Register RELR0. If a bit in Register REMR0 is set to One, the corresponding bit in Register RELR0 will be applied to the Interrupt Condition Register, which can then be used to generate an interrupt.

D1	MYBCN	My__Beacon Mask: This bit is used to mask RELR1.MYBCN.
D0	OTRBCN	Other__Beacon Mask: This bit is used to mask RELR1.OTRBCN.

7.0 Control Information (Continued)

Token and Timer Event Latch Register 0 (TELRO)

The Token and Timer Event Latch Register 0 (TELRO) informs software of time expirations of the Token Rotation Timer (TRT) and Valid Transmission Timer (TVX). The TELRO Register also reports token events such as duplicate token detection, restricted token reception, and general token capture and release. The completion of the Ring Latency measurement is also indicated in the TELRO Register. Each bit may be masked via the Token and Timer Event Mask Register (TEMRO).

D0	FRCV	Frame Received Counter Overflow Mask: This bit is used to mask COLR.FRCV.

7.0 Control Information (Continued)

Internal Event Latch Register (IELR)

The Internal Event Latch Register (IELR) reports internal errors in the Ring Engine. These errors include MAC Parity errors and inconsistencies in the Receiver and Transmitter state machines.

After an internal state machine error is detected and reported (bit RSMERR for the receiver and TSMERR for the transmitter), the Current Receive Status Register (CRS0) and Current Transmit Status Register (CTS0) continue to be updated as normal.

In Diagnose mode (Mode.Diag = 1), the Current Receive Status Register and Current Transmit Status Register are frozen with the errored state until the internal state machine error condition is cleared (bit RSMERR and/or TSMERR is set to Zero).

Errors internal to the Ring Engine cause a MAC_Reset.

Access Rules

Address	Read	Write
028h	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
RES	RES	RES	RES	TSMERR	RSMERR	RES	MPE

Bit	Symbol	Description
D7–D4	RES	Reserved
D3	TSMERR	Transmit State Machine Error: Indicates inconsistency in the Transmitter state machine. When set, causes bit MCRST of the Function Register to be set.
D2	RSMERR	Receive State Machine Error: Indicates inconsistency in the Receiver state machine. When set, causes bit MCRST of the Function Register to be set.
D1	RES	Reserved
D0	MPE	MAC Interface Parity Error: Indicates a Parity Error on the MAC Request Data bus (the internal bus MRD (7:0) between the SI and MAC blocks) when parity is enabled on the MA_Request Interface (bits MRP of the MAC Mode Register 0 (MCMR0)) are set and pin TXACK is asserted).

7.0 Control Information (Continued)

Exception Status Register (ESR)

The Exception Status Register (ESR) reports errors to the software. Errors include PHY Interface Parity Errors, illegal attempts to access currently inaccessible registers, and writing to a conditional write location if a register bit has changed since it was last read. Each bit may be masked via the Exception Mask Register (EMR).

Access Rules

Address	Read	Write
02Ch	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
CWI	CCE	CPE	RES	RES	RES	RES	PPE

Bit	Symbol	Description
D7	CWI	Conditional Write Inhibit: Indicates that at least one bit of the previous conditional write operation was not written. This bit is set unconditionally after each write to a conditional write register if the value of the Compare Register is not equal to the value of the register that was accessed for a write before it was written. This may indicate that the accessed register has changed since it was last read. This bit is cleared after a successful conditional write. This occurs when the value of the Compare Register is equal to the value of the register that was accessed for a write before it was written. CWI does not contribute to setting the ESE bit of the Interrupt Condition Register (it is always implicitly masked).
D6	CCE	Control Bus Command Error: Indicates that a Control Bus command was not performed due to an error, i.e., illegal command or a Control Bus Write Parity Error. An illegal command is an attempt to access a currently inaccessible register.
D5	CPE	Control Bus Parity Error: Indicates a Control Bus Parity Error was detected on the Control Bus Data pins (CBD7–0) during a write operation to a register. Parity errors are reported if parity is enabled on the Control Bus Interface (bit CBP of the Mode Register is set).
D4–D1	RES	Reserved
D0	PPE	PHY Interface Parity Error: Indicates parity error detected on PID7–0. Parity errors are reported when parity is enabled on the PHY_Request Interface (bit PIP of the Mode Register is set).

7.0 Control Information (Continued)

Exception Mask Register (EMR)

The Exception Mask Register (EMR) is used to mask bits in the Exception Status Register (ESR). If a bit in Register EMR is set to One, the corresponding bit in Register ESR will be applied to the Condition Register, which can then be used to generate an interrupt.

All bits in this register are set to Zero upon reset.

Access Rules

Address	Read	Write
02Dh	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
ZERO	CCE	CPE	RES	RES	RES	RES	PPE

Bit	Symbol	Description
D7	ZERO	Zero: This bit is always Zero. This implies that the CWI bit never contributes to the Interrupt Signal.
D6	CCE	Control Bus Error Mask: This bit is used to mask ESR.CCE.
D5	CPE	Control Bus Parity Error Mask: This bit is used to mask ESR.CPE.
D4–D1	RES	Reserved
D0	PPE	PHY Interface Parity Error Mask: This bit is used to mask ESR.PPE.

7.0 Control Information (Continued)

Interrupt Condition Register (ICR)

The Interrupt Condition Register (ICR) collects unmasked interrupts from the Event Registers. Interrupts are categorized into Ring Events, Token and Timer Events, Counter Events, and Error and Exceptional Status Events. If the bit in the Interrupt Mask Register (IMR) and the corresponding bit in the ICR are set to One, the INT0 pin is forced low and thus triggers an interrupt.

Note: Bits are cleared ONLY by clearing underlying conditions (Mask bit and/or Event Bit) in the appropriate Event Register.

Access Rules

Address	Read	Write
02Eh	Always	Data Ignored

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0

D1	TTE	Token and Timer Event Mask: This bit is used to mask ICR.TTE.
D0	RNG	Ring Event Mask: This bit is used to mask ICR.RNG.

7.0 Control Information (Continued)

7.5 MAC PARAMETERS

The MAC Parameters are accessible in the Stop Mode. These parameters are also accessible in the Run Mode when the following conditions are met:

- the MAC Transmitter is in state T0, T1, or T3; and
- bits ITC and IRR of the Option Register are set to One; and
- bits CLM and BCN of the Function Register are set to Zero.

Otherwise read and write accesses will cause a command error (bit CCE of the Exception Status Register is set to One) and the access will not be performed.

The MAC Parameters are stored in the MAC Parameter RAM. They include the following control information:

- Individual Addresses: My Long Address (MLA0–5) and My Short Address (MSA0–1).
- Group Addresses: Group Long Address (GLA0–4) and Group Short Address (GSA0), Programmable Group Map (PGM0–F), and Fixed Group Map (FGM0–1).
- MAC Frame Information: Requested Target Token Rotation Time (TREQ0–3) and Transmit Beacon Type (TBT0–3)

7.5.1 Individual Addresses

The Ring Engine supports both Long and Short Individual Addresses simultaneously. The Station's Long Address is stored in registers MLA0–5. The Station's Short Address is stored in registers MSA0–1.

For received frames, MLA or MSA is compared with the received DA in order to set the Address recognized Flag (A_Flag) and compared with the received SA in order to set the My Address recognized Flag (M_Flag). In transmitted frames, MLA or MSA normally replaces the SA from the frame data stream (exception: when SA transparency is used).

Bits MLA(47) and MSA(15) are the most significant bits of the address and are transmitted and received first. Bits MLA(0) and MSA(0) are the least significant bits of the address and are transmitted and received last.

MLA and MSA should be valid for at least 12 byte times before the Addressing Mode is enabled and should remain valid for at least 12 byte times after the Addressing Mode is disabled in order to guarantee proper detection.

Bits ELA (Enable Long Addressing) and ESA (Enable Short Addressing) in the Option Register determine the address types that may be recognized and generated by this MAC.

My Long Address (MLA0–MLA5)

My Long Address (MLA0–MLA5) represent this station's long 48-bit address.

Access Rules

Address	Read	Write

Note: MSA(15) should always be set to 0.

7.0 Control Information (Continued)

7.5.2 Group Addresses

The Ring Engine supports detection of Group Addresses within programmable and fixed blocks of consecutive addresses. The algorithm used by the Ring Engine first performs a comparison between the most significant bits of the received DA with programmable and fixed addresses. If the most significant bits match, the remaining bits are used as an index into a programmable bit map. If the indexed bit is 1, the A_Flag is set to 1; if the indexed bit is 0, the A_Flag remains 0.

One programmable block of 256 group addresses is supported for group long addresses (GLA) and one programmable block of group addresses is supported for group short addresses (GSA). Both of the programmable ranges share the same programmable group address map (PGM).

For short addresses, the first byte of a received DA is compared with GSA0 (bits GSA(15–8)). If they match then the second byte is used as an index into the PGM. For long addresses the first 5 bytes of a received DA are compared with GLA0 through GLA4 (bits GLA(47–8)). If all 5 of these bytes match the corresponding byte in the received DA, then the 6th byte of the received DA is used as an index into the PGM. The last byte of the address is used as an index into the PGM in both long and short group addressing.

A fixed block of 16 group addresses is supported for both long and short addresses at the end of the address space that includes the Universal/Broadcast Address (FF . . . FF). For short addresses, if the first 12 bits of the received DA are all 1's then the last 4 bits are used as an index into the 16-bit Fixed Group Map (FGM). Similarly, for long addresses if the first 44 bits are all 1's, the last 4 bits are also used as an index into the 16-bit FGM.

The Group Addresses should be valid for at least 12 byte times before the Addressing Mode is enabled and should remain valid for at least 12 byte times after the Addressing Mode is disabled in order to guarantee proper detection.

Bits ELA (Enable Long Addressing) and ESA (Enable Short Addressing) in the Option Register determine the address types that will be recognized by this MAC.

Alternative group addressing schemes may be implemented using external matching logic that monitors the byte stream at the PHY Interface. The result of the comparison is returned using the EA (External A_Flag) input signal.

Group Long Address (GLA0–GLA4)

Group Long Address (GLA0–GLA4) represents the first 5 bytes of the long address, bit GLA(47) to bit GLA(8).

To disable Long Group Address matches, bits GLA(46–8) should be set to all One's.

Access Rules

Address	Read	Write
048–04Ch	Stop Mode	Stop Mode

Register Bits

	D7	D6	D5	D4	D3	D2	D1	D0
GLA0	GLA(47)	GLA(46)	GLA(45)	GLA(44)	GLA(43)	GLA(42)	GLA(41)	GLA(40)
GLA1	GLA(39)	GLA(38)	GLA(37)	GLA(36)	GLA(35)	GLA(34)	GLA(33)	GLA(32)
GLA2	GLA(31)	GLA(30)	GLA(29)	GLA(28)	GLA(27)	GLA(26)	GLA(25)	GLA(24)
GLA3	GLA(23)	GLA(22)	GLA(21)	GLA(20)	GLA(19)	GLA(18)	GLA(17)	GLA(16)
GLA4	GLA(15)	GLA(14)	GLA(13)	GLA(12)	GLA(11)	GLA(10)	GLA(9)	GLA(8)

Note: GLA(47) should always be set to One.

Group Short Address (GSA0)

Group Short Address (GSA0) represents the station's short 16-bit address, bit GSA(15) to bit GSA(8).

It is possible to disable Short Group Addressing by programming bits GSA(14–8) to all Ones.

Access Rules

Address	Read	Write
04Eh	Stop Mode	Stop Mode

Register Bits

	D7	D6	D5	D4	D3	D2	D1	D0
GSA0	GSA(15)	GSA(14)	GSA(13)	GSA(12)	GSA(11)	GSA(10)	GSA(9)	GSA(8)

Note: GSA(15) is not used in the comparison since the comparison will only be accomplished if the received DA(15) is a One.

7.0 Control Information (Continued)

Fixed Group Address MAP (FGM0–FGM1)

If the first 44 bits of a long DA, DA(47–4), or the first 12 bits of a short DA, DA(15–4) are 1, the last 4 bits of the DA, DA(3–0), are used as an index into FGM.

The 4-bit index into FGM can be viewed in two different ways. It can be viewed as 4 bits selecting one of 16 bits where the hexadecimal equivalent of DA(3–0) can be used as the index. For example the broadcast address would index FGM(F). Alternatively it can be viewed as one bit, DA(3), selecting the byte (FGM0 or FGM1) and three bits, DA(2–0) selecting one of 8 bits within a byte.

Access Rules

Address	Read	Write
058–059h	Stop Mode	Stop Mode

Register Bits

	D7	D6	D5	D4	D3	D2	D1	D0
FGM0	FGM(7)	FGM(6)	FGM(5)	FGM(4)	FGM(3)	FGM(2)	FGM(1)	FGM(0)
FGM1	FGM(F)	FGM(E)	FGM(D)	FGM(C)	FGM(B)	FGM(A)	FGM(9)	FGM(8)

Bit FGM(F) must be set to One to ensure proper handling of frames with the Universal/Broadcast address including the SMT NSA frames. This is mandatory for interoperability on an FDDI Ring.

Programmable Group Address MAP (PGM0–PGM1F)

If the first 40 bits of a long DA, DA(47–8), match the GLA or the first 8 bits of a short DA, DA(15–8), match the GSA, the last 8 bits of the DA are used as an index into PGM.

The 8-bit index into PGM can be viewed in two different ways.

- As 8 bits selecting one of 256 bits where the hexadecimal equivalent of DA(7–0) can be used as the index. For example a DA with the last byte as A2h indexes PGM(A2).
- As 5 bits, DA(7–3), selecting the byte (PGM0 to PGM1F) and three bits, DA(2–0) selecting one of 8 bits within a byte. For example a DA with the last byte of A2h (1010 0010b) selects PGM14 bit 2.

It is possible to disable Long and Short Group Addressing by filling the Group Address Map with 0's.

In the MACSI device, PGM(00) to PGM(7F) are set equal to PGM(80) to PGM(FF) and are accessible via the Control Interface. This implies that DA(7) of group addresses is a don't care.

7.5.3 Claim Information: Requested Target Token Rotation Time (TREQ)

The Requested Target Token Rotation Time is stored in registers TREQ0–TREQ3. TREQ(31–0) is represented as a negative two's complement number. This value is transmitted in all Claim frames generated by the Ring Engine.

Bits TREQ(31–24) are always transmitted as and compared with FFh and bits TREQ(7–0) are always transmitted as and compared with 00h, independent of the value stored in the MAC Parameter RAM. Bit TREQ(0) is transmitted last. TREQ is therefore programmable with 20.48 μ s resolution and a maximum value of 1.34 seconds.

Access Rules

7.0 Control Information (Continued)

7.5.4 Beacon Information: Transmit Beacon Type (TBT)

Transmit Beacon Type 0 (TBT0) represents the Transmit Beacon Type to be transmitted in the Information field of a Beacon frame. TBT1–TBT3 are not used by the Ring Engine.

When the Beacon state is reached as a result of a failed Claim process, the first byte of the Beacon Information field is forced to Zero to produce a Beacon Type 0 as required by the MAC Standard.

When the Beacon state is reached as a result of a Beacon Request (when Function.BCN is set), bits TBT(31–24) are transmitted as the Information field.

7.6 TIMER VALUES

The Ring Engine stores several timer values and thresholds used in normal operation. With the exception of TNEG, the Timers use an exponential expansion on a 4-bit value to produce a negative two's complement 24-bit value used by the Timer Logic.

The Timer Values are always readable. These parameters are writable in Stop Mode.

The Timers include the following timers:

- Asynchronous Priority Threshold (THSH1)
- Maximum Token Rotation Time (TMAX)
- Valid Transmission Timer (TVX)
- Negotiated Target Rotation Time (TNEG0–3)

7.0 Control Information (Continued)

7.6.1 Asynchronous Priority Threshold (THSH1)

The Ring Engine currently supports one Asynchronous Priority Threshold in addition to the default threshold at TTRT. The Asynchronous Priority Threshold is used in a magnitude comparison with THT when an Asynchronous Priority Request is presented to the MAC Request Interface.

Bits 7–4 are always written to Zero and are always read as Zero.

When more than one threshold is used, the users of THSH1 have the lowest priority. All asynchronous transmissions are limited by TTRT. If the Late Flag is set, no frames may be transmitted, regardless of the value of the Asynchronous Priority Threshold.

Access Rules

B	20.972 ms
C	41.943 ms (default)
D	83.886 ms
E	167.77 ms
F	335.54 ms

Warning: The default value may not be appropriate for all values of TNEG. In some cases, this could result in a request that is NEVER serviced.

7.0 Control Information (Continued)

7.6.2 Maximum Token Rotation Time (TMAX)

The Maximum Token Rotation Time (TMAX) denotes the maximum Target Token Rotation Time supported by this station. TMAX is stored as a 4-bit value that is expanded to a binary exponential value. Bits 7–4 are ignored during write operations and are always read as Zero.

TMAX has a maximum value of 1.34 seconds with a threshold of $40.96 \times 2^{TMAX} \mu\text{s}$. On a Master Reset (Function.MARST set to One), TMAX is set to the value of Ch which corresponds to 167.772 ms, the default specified by the FDDI MAC Standard.

For immediate transmissions from the transmit data state (T2), TMAX is always used to enforce an upper bound on the amount of time a station may transmit. TRT is reset to TMAX on entry to state T2 on immediate requests.

F	1.3422 s

7.0 Control Information (Continued)

7.6.3 Valid Transmission Time (TVX)

The Valid Transmission Timer (TVX) is used to increase the responsiveness of the ring to errors that cause ring recovery. The TVX value denotes the maximum time in which a valid frame or token should be seen by this station. TVX is stored as a 4-bit value that is expanded to a binary exponential value. Bits 7–4 are ignored during write operations and read as Zero.

TVX has a maximum value of 1.34 seconds with a threshold of $40.96 \times 2^{\text{TVX}} \mu\text{s}$. On a Master Reset TVX is set to the value of 6h which corresponds to 2.62 ms, the default specified by the FDDI MAC Standard.

D	335.54 ms
E	671.09 ms
F	1.3422 s

7.0 Control Information (Continued)

Negotiated Target Rotation Time (TNEG0–3)

The Negotiated Target Rotation Time (TNEG0–3) is a 32-bit twos complement value. It is the result of the Claim process. TNEG is loaded either directly from the received Claim Information field (T_Bid_Rc) or via the Control Interface.

The first byte of TNEG (bits TNEG(31–24)) always contains FFh. TNEG has a maximum value of 1.34 seconds and a resolution of 80 ns.

TRT is loaded with TNEG when the Ring_Operational flag is set. TNEG is not automatically compared with TREQ when the Ring_Operational flag is set. This should be checked by software whenever the ring becomes operational to make sure that TNEG is less than or equal to TREQ.

An implementation of the SM_Control.Request (Reset) should load TNEG with TMAX to remove any possibility of the station entering Claim early.

On a Master Reset (bit MARST in the Function Register is set), TNEG is set to FFE00000, which corresponds to 167.772 ms, the default TMAX specified by the FDDI MAC Standard.

7.7 EVENT COUNTERS

The Event Counters are used to gain access to the internal 20-bit counters used to gather statistics.

The following event counters are included:

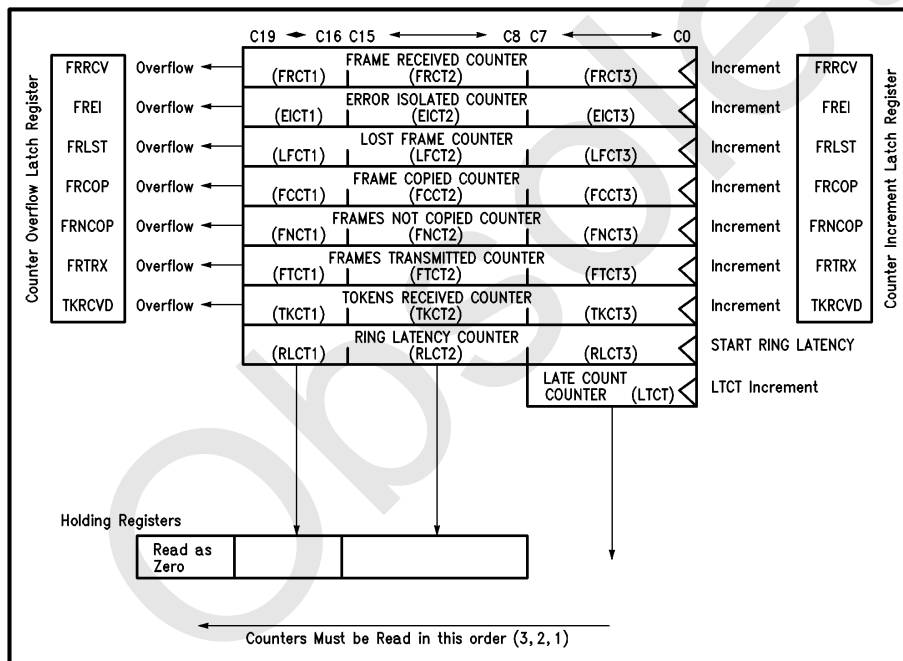

- Frame Received Counter (FRCT1–3)
- Error Isolated Counter (EICT1–3)
- Lost Frame Counter (LFCT1–3)
- Frame Copied Counter (FCCT1–3)
- Frame Not Copied Counter (FNCT1–3)
- Frame Transmitted Counter (FTCT1–3)
- Token Received Counter (TKCT1–3)
- Ring Latency Counter (RLCT1–3)
- Late Count Counter (LTCT)

7.7.1 Processing Procedures

The counters are 20-bit wrap-around counters except for the Late Count Counter which is a 4-bit sticky counter (see *Figure 7-2*).

Since the Control Bus Interface is an 8-bit interface and the counters are 20 bits wide, a register holding scheme is implemented. In order to provide a consistent snapshot of a counter, while the least significant byte is read, the upper 12 bits are loaded into a holding register which can then be read. The least significant byte must be read first.

The Counters are always readable and are writable in Stop Mode. The Counters are not reset as a result of a Master Reset. This may be done by either reading the Counters out and keeping track relative to the initial value read, or by writing a value (Zero) to all of the Counters in Stop Mode. The Counters may be written in any order. Interrupts may be requested when the counters increment (except for Ring Latency Counter) or wrap-around (except for Ring Latency Counter and Late Count Counter).

TL/F/11705-45

FIGURE 7-2. Event Counters

7.0 Control Information (Continued)

Late Count Counter (LTCT)

The Late Count Counter (LTCT) is implemented differently than suggested by the FDDI MAC Standard, but provides similar information. The function of the Late Count Counter is divided between the Late_Flag and a separate counter. The Late_Flag is equivalent to the Standard Late Count with a non-zero value. It is maintained by the Ring Engine to indicate if it is possible to send asynchronous traffic. When the ring is operational, Late Count indicates the time it took the ring to recover the last time the ring went non-operational. When the ring is non-operational, Late Count indicates the time it has taken (so far) to recover the ring.

The Late Count is provided to assist Station Management in the isolation of serious ring errors. In many situations, it is helpful for SMT to know how long it has been since the ring went non-operational in order to determine if it is necessary to invoke recovery procedures. When the ring becomes non-operational, there is no way to know how long it will stay non-operational, therefore a timer is necessary. If the Late Count Counter is not provided, SMT would be forced to start a timer every time the ring goes non-operational even though it may seldom be used. By using the provided Late Count Counter, an SMT implementation may be able to alleviate this additional overhead.

The Late Count Counter is incremented every time TRT expires while the ring is non-operational and Late_Flag is set (once every TMAX). This counter is never writable, not even in Stop Mode. The counter is set to Zero as a result of a MAC Reset when a Beacon or Claim Request is not also present (Function.MCRST is set and Function.BCN and Function.CLM are not set) and every time the ring becomes non-operational. Late Count Counter is a sticky counter at 15.

Events reported in the Token and Timer Event Latch Register (TELRO.CBERR, TELRO.TRTEXP) can be used to determine that Late Count Counter has incremented. No overflow event is provided.

Frame Received Counter (FRCT)

The Frame Received Counter (FRCT) is specified in the FDDI MAC Standard. It is the count of all complete frames received including MAC frames, Void frames and frames stripped by this station.

Interrupts are available on increment (CILR.FRRCV) and when the 20-bit counter overflows and wraps around (COLR.FRRCV).

FRCT3	CT7	CT6	CT5	CT4	CT3	CT2	CT1	CT0

Error Isolated Counter (EICT)

The Error Isolated Counter (EICT) is specified in the FDDI MAC Standard. It is the count of all error frames detected by this station and no previous station.

It is incremented when:

1. an FCS error is detected and the received Error Indicator (Er) is not equal to S; or
2. a frame of invalid length (i.e., off-boundary T) is received and Er is not equal to S; or
3. Er is not R or S

Interrupts are available on increment (CILR.FREI) and when the 20-bit counter overflows and wraps around (COLR.FREI).

7.0 Control Information (Continued)

Lost Frame Counter (LFCT)

The Lost Frame Counter (LFCT) is specified in the FDDI MAC Standard. It is the count of all instances where a Format Error is detected in a frame or token such that the credibility of the PDU reception is in doubt.

The Lost Frame Counter is incremented when any symbol other than a data or Idle symbol is received between the Starting and Ending Delimiters of a PDU (this includes parity errors).

Interrupts are available on increment (CILR.FRLST) and when the 20-bit counter overflows and wraps around (COLR.FRLST).

LFCT3	CT7	CT6	CT5	CT4	CT3	CT2	CT1	CT0

Frame Copied Counter (FCCT)

The Frame Copied Counter (FCCT) maintains the count of the number of frames addressed to this station and successfully copied. This counter can be used to accumulate station performance statistics.

The Frame Copied Counter is incremented when a frame which contains no errors and is addressed to this station is successfully copied. Copied MAC and Void frames are not included in this count.

When Option.EMIND is set, this count also includes frames copied as a result of external matches as indicated by EA.

For SMT NSA frames, the Frame Copied Count only increments for NSA frames received with the A Indicator as an R symbol for which the frame was copied. SMT NSA frames received with the A Indicator as an S symbol do not cause this count to increment, even if the frame is successfully copied.

Note that when in a promiscuous copy mode, this count will not increment for every frame copied, only for frames addressed to this station that are copied.

Interrupts are available on increment (CILR.FRCOP) and when the 20-bit counter overflows and wraps around (COLR.FRCOP).

7.0 Control Information (Continued)

Frame Not Copied Counter (FNCT)

The Frame Not Copied Counter (FNCT) maintains a count of the number of frames intended for this station that were not successfully copied by this station. This count can be used to accumulate station performance statistics such as insufficient buffering or deficient frame processing capabilities for frames addressed to this station.

The Frame Not Copied Counter is incremented when an internal match occurs on the Destination Address, no errors were detected in the frame, and the frame was not successfully copied (internal VCOPY signal not asserted by the System Interface). Not Copied MAC frames and Void frames are not included in this count.

When Option.EMIND is set this count also includes frames not copied on external matches indicated by EA.

The handling of SMT NSA frames follows the MAC-2 Draft Standard. For SMT NSA frames, the Frame Not Copied Count only increments for NSA frames received with the A Indicator as an R symbol for which the frame was not copied. SMT NSA frames received with the A Indicator as an S symbol do not cause this count to increment, even if the frame is not successfully copied. Interrupts are available on increment (CILR.FRNCOP) and when the 20-bit counter overflows and wraps around (COLR.FRNCOP).

Frame Transmitted Counter (FTCT)

The Frame Transmitted Counter (FTCT) maintains the count of frames transmitted successfully by this station. The counter can be used to accumulate station performance statistics.

The Frame Transmitted Counter is incremented every time a complete frame is transmitted from the MAC Request Interface. MAC and Void frames generated by the Ring Engine are not included in the count.

Interrupts are available on increment (CILR.FRTRX) and when the 20-bit counter overflows and wraps around (COLR.FRTRX).

7.0 Control Information (Continued)

Token Received Counter (TKCT)

The Token Received Counter (TKCT) maintains the count of valid tokens received by this station. The counter can be used with the Ring Latency Counter to calculate the average network load over a period of time. The frequency of token arrival is inversely related to the network load.

The Token Received Counter is incremented every time a valid token arrives.

Interrupts are available on increment (CILR.TKRCVD) and when the 20-bit counter overflows and wraps around (COLR.TKRCVD).

Ring Latency Counter (RLCT)

The Ring Latency Counter (RLCT) is a measurement of time for PDUs to propagate around the ring. This counter contains the last measured ring latency whenever the RLVD bit of the Token and Timer Event Latch Register (TELRO.RLVD) is One.

The current ring latency is measured by timing the propagation of a My_Void frame around the ring. A new latency measurement can be requested by clearing the Ring Latency Valid bit of the Token Event Register (TELRO.RLVLD).

When the ring is operational, the next early token is captured. Before the token is re-issued, a My_Void frame is transmitted and the Ring Latency Counter (RLCT) is reset. The token will not be captured if the Inhibit Token Capture Option (Option.ITC) is set and the ring latency will not be measured.

When the ring is not operational, ring latency timing will commence at the end of the next immediate request. A My_Void is transmitted and RLCT is reset. This could be used to time how long the ring is non-operational since the My_Void frame will not return.

The Ring Latency Counter increments once every 16 byte times from when the Ending Delimiter of the My_Void frame is transmitted, until the Ending Delimiter of the My_Void frame returns. When the My_Void frame returns, the ring latency valid bit (TELRO.RLVLD) is set and may cause an interrupt. When set, RELR.RLVLD indicates that RLCT will be valid to within 1.28 μ s. The Ring Latency Counter can measure ring latencies up to 1.3421772 seconds with accuracy of 1.28 μ s.

The ring latency timing function is automatically disabled when exceptions are detected and retried at the next opportunity.

Since a Master Reset (Function.MARST) causes TELRO.RLVLD to be cleared, the ring latency will automatically be measured on the first opportunity (at the end of the first immediate request or with the first early token). Note that if a duplicate of this MAC address exists on the ring, the My_Void frame will be stripped and the ring latency measurement will never complete.

7.0 Control Information (Continued)

System Interface Mode Register 0 (SIMR0)

The System Interface Mode Register 0 (SIMR0) is used to program major operating parameters for the System Interface of the MACSI device. This register should be programmed only at power-on, or after a software Master Reset.

This register is cleared upon reset.

Access Rules

Address	Read	Write
100h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
SMLB	SMLQ	VIRT	BIGEND	FLOW	MRST	FABCLK	TEST

Bit	Symbol	Description
D0	TEST	Test Mode: Enables test logic, in which the transmitted frames counter will cause a service loss after four frames, instead of 255 frames.
D1	FABCLK	Fast ABus Clock: For any AB__CLK frequency greater than LBC (12.5 MHz), this bit must be zero. For an AB__CLK frequency equal to LBC, the User may optionally set this bit. Setting this bit causes a slight optimization of the internal MACSI synchronization timing valid only for the case where AB__CLK = LBC = 12.5 MHz. National recommends that all users leave this bit as zero.
D2	MRST	Master Reset: When this bit is set, the indicate, Request, and Status/Space Machines are placed in Stop Mode, and System Interface registers are initialized to the values shown in Table 7-2. This bit is cleared after the reset is complete.
D3	FLOW	Flow Parity: When this bit is set, parity checking is enabled at the MAC Indicate Data (Receive Data) interface. The MACSI device uses Odd parity at all interfaces. The System Interface reports parity errors in the STAR.BPE bit (for receive data from the MAC) or the STAR.ERR (for descriptor fetch parity errors). Data parity does not get checked at the ABus Interface. When this bit is set, the parity bit for each ABus data byte flows with the data byte through the internal FIFO and across the MAC Request (Transmit) interface where it is checked by the Ring Engine. Good parity is always generated on ABus. If this bit is reset, good parity is generated at the MAC Request interface. For the MAC Indicate Data interface, the parity check includes the frame's FC through ED fields. When this bit is Zero, no parity is checked on the MAC Indicate Data interface. In the BSI device, this bit also controlled the Control Bus Parity. In the MACSI device, Control Bus Parity is enabled using the MCMODE.CBP bit (see "MAC Mode Register 0 (MCMR0)"). For systems using parity on the ABus, the User must initialize the Receive burst FIFO RAM after reset by doing a send-to-self of a frame at least 64 bytes in length.
D4	BIGEND	Big Endian Data Format: Selects between the Little Endian (BIGEND = 0) or Big Endian (BIGEND = 1) data format. See <i>Figure 6-1</i> .
D5	VIRT	Virtual Address Mode: Selects between virtual (VIRT = 1) or physical (VIRT = 0) address mode on the ABus.
D6	SMLQ	Small Queue: Selects the size of all Descriptor queues and lists. When SMLQ = 0, the size is 4 kBytes; when SMLQ = 1, the size is 1 kBytes. Note that data pages are always 4 kBytes.
D7	SMLB	Small Bursts: Selects size of bursts on ABus. When SMLB = 0, the MACSI device uses 1-, 4-, and 8-word transfers. When SMLB = 1, the MACSI device uses 1- and 4-word transfers.

D1	RES	Reserved																																																																	
D2	ASM	<p>Address Strobe Mode: The ASM bit controls the Address Strobe Mode. When this bit is reset, the $\overline{AB_AS}$ signal operates as it does on the BSI device. When this bit is set, the MACSI device generates an $\overline{AB_AS}$ signal which is designed to drive an address latch control line without additional logic (see <i>Figure 6-6</i> and <i>Figure 6-7</i>).</p>																																																																	
D3	ATM	<p>Address Timing Mode: The ATM bit controls the Address Timing Mode. When this bit is reset, the AB_A(4:2) lines operate as they do on the BSI. These lines provide the demultiplexed address of the next word to be accessed on the ABus. When the ATM bit is set, the MACSI device provides the address of the <i>current</i> word being accessed on the ABus (see <i>Figure 6-6</i> and <i>Figure 6-7</i>). To use the demultiplexed address pins AB_A (27:2) on MACSI revision A through C, the User must set the ATM bit. For MACSI revision D and later (SI revision \geq 0x00000058), the User may use the demultiplexed address pins AB_A (27:2) with ATM set or reset.</p>																																																																	
D7-D4	AB_A(31:28)	<p>AB_Address(31:28): In normal operation (MR1.EAM = 0), the MACSI device encodes channel information on the upper nibble of the AB_AD bus during the address cycle. In Enhanced ABus mode (MR1.EAM = 1), the upper nibble of the address lines are driven with the data pattern which the user has stored in these four bits, AB_A(31:28).</p>																																																																	

7.0 Control Information (Continued)

Pointer RAM Control and Address Register (PCAR)

The Pointer RAM Control and Address Register (PCAR) is used to program the parameters for the PTOp (Pointer RAM Operation) service function, in which data is written to or read from a Pointer RAM Register.

This register is not altered upon reset.

Access Rules

Address	Read	Write
102h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
BP1	BP0	PTRW	A4	A3	A2	A1	A0

Bit	Symbol	Description
D4–D0	A4–A0	Pointer RAM Address: These five bits contain the Pointer RAM Register address for a subsequent PTOp service function.
D5	PTRW	PTOp Read/Write: This bit determines whether a PTOp service function will be a read from the Pointer RAM Register to the mailbox in memory (PTRW = 1), or a write to the Pointer RAM Register from the mailbox (PTRW = 0).
D7–D6	BP1–BP0	Byte Pointer: These two bits are used to program an internal byte pointer for accesses to the 28-bit Mailbox Address Register. They are normally set to Zero to initialize the byte pointer for four successive writes (most-significant byte first) and are automatically incremented after each write. Because this register is not altered upon reset, it is important that these bits be explicitly configured before accessing the Mailbox Address Register.

Mailbox Address Register (MBAR)

The Mailbox Address Register (MBAR) is used to program the word-aligned 28-bit memory address of the mailbox used in the data transfer of the PTOp (Pointer RAM Operation) service function.

The address of the register is used as a window into four internal byte registers. The four byte registers are loaded by successive writes to the address after first setting the BP1–0 bits in the Pointer RAM Control and Address Register to Zero. The bytes must be loaded most-significant byte first. The MACSI device increments the byte pointer internally after each write or read. Mailbox Address bits 0 and 1 forced internally to Zero.

The four internal byte registers are initialized to a 28-bit System Interface Revision code upon reset. The System Interface Revision code remains until it is overwritten by the host. The BP1–0 bits in the PCAR must be initialized before accessing the MBAR to fetch the System Interface Revision code.

Master Attention Register (MAR)

The Master Attention Register (MAR) collects enabled attentions from the State Attention Register, Service Attention Register, No Space Attention Register, Request Attention Register, and Indicate Attention Register. If the Notify bit in the Master Notify Register and the corresponding bit in the MAR are set to One, the $\overline{INT1}$ pin is forced to LOW and thus triggers an interrupt.

Writes to the Master Attention Register are permitted, but do not change the contents.

All bits in this register are set to Zero upon reset.

106h	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
ERR	BPE	CPE	CWI	CMDE	SPSTOP	RQSTOP	INSTOP

Bit	Symbol	Description
D0	INSTOP	<p>Indicate Stop: This bit is set by the host to place the Indicate Machine in Stop Mode. It is also set upon reset. Three different conditions cause the MACSI device to set this bit. The first is an internal error. This is caused by a bad tag read out of the Indicate Data FIFO. This is a hardware error. The next condition is an invalid state. This is a hardware error where the Indicate Machine state bits contain an illegal pattern. The final condition is when the user programs an illegal header length for Header/Info sorting mode. An invalid value is any value less than four words.</p> <p>This bit is set by serious hardware failures or illegal software operations. Therefore it is recommended that the entire MACSI device be reset if this bit should get set during normal operation.</p>
D1	RQSTOP	<p>Request Stop: This bit is set by the host to place the Request Machine in Stop Mode. It is also set upon reset. The MACSI device will set this bit if it detects that the Request Machine has entered an illegal state. This is a hardware error. The MACSI device will also set this bit if an ABus error is detected during any Request Operation. This includes REQ, ODUD, and ODU fetches, and CNF writes.</p> <p>This bit is set by serious hardware failures or ABus errors. Therefore it is recommended that the entire MACSI device be reset if this bit should get set during normal operation.</p>
D2	SPSTOP	<p>Status/Space Stop: This bit is set by the host to place the Status/Space Machine in Stop Mode. It is also set upon reset. In addition, the MACSI device will set this bit upon detecting an unrecoverable error. An unrecoverable error is an ABus error during a PSP fetch or a Pointer RAM Operation, (PTOP). In STOP Mode, only PTOP or LMOP service functions may be performed.</p> <p>This bit is set by ABus errors during critical Status/Space operations. Therefore it is recommended that the entire MACSI device be reset if this bit should get set during normal operation. This reset should include reloading of Pointer RAM values and restarting the PSP queues.</p>
D3	CMDE	<p>Command Error: Indicates that the host performed an invalid operation. This occurs when an invalid value is loaded into the Indicate Header Length Register (which also sets the INSTOP attention). This bit is cleared upon reset.</p> <p>This bit is set when software performs an illegal operation. This indicates either a software bug or the improper operation of the processor. Therefore it is recommended that the entire MACSI device be reset if this bit should get set during normal operation.</p>
D4	CWI	<p>Conditional Write Inhibit: Indicates that at least one bit of the previous conditional write operation was not written. This bit is set unconditionally after each write to a conditional write register. It is also set when the value of the Compare Register is not equal to the value of the register that was accessed for a write before it was written. This may indicate that the accessed register has changed since it was last read. This bit is cleared after a successful conditional write. CWI bit does not contribute to setting the STA bit of the Master Attention Register because its associated Notify bit is always 0. This bit is cleared upon reset.</p>
D5	CPE	<p>Control Bus Parity Error: Indicates a parity error detected on CBD7–0. If there is a Control Bus parity error during a host write, the write is suppressed. Control Bus parity errors are reported when flow-through parity is enabled (the FLOW bit of the Mode Register is set). This bit is cleared upon reset.</p>
D6	BPE	<p>BMAC Device Parity Error: Indicates parity error detected on MID7–0. This bit is cleared upon reset. This bit is only set if FLOW (parity enable) is set and the error occurred on a frame that the MACSI device has decided to copy or if it occurred before the copy decision was made.</p>
D7	ERR	<p>Error: This bit is set by the MACSI device when a non-recoverable error occurs. This includes any ABus transaction error or an internal state machine error. For MACSI revision D or later, a descriptor fetch parity error will also set this bit if the User has enabled parity checking via the SIMR0.FLOW bit. This bit is cleared upon reset.</p>

7.0 Control Information (Continued)

State Notify Register (STNR)

The State Notify Register (STNR) is used to enable bits in the State Attention Register (STAR). If a bit in the STNR is set to One, the corresponding bit in Register STAR will be applied to the Master Attention Register, which can be used to generate an interrupt to the host.

All bits in this register are cleared to Zero upon reset.

Access Rules

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
ERRN	BPEN	CPEN	CWIN	CMDEN	SPSTOPN	RQSTOPN	INSTOPN

Bit	Symbol	Description
D0	INSTOPN	Indicate Stop Notify: This bit is used to enable the INSTOP bit in Register STAR.
D1	RQSTOPN	Indicate Stop Notify: This bit is used to enable the RQSTOP bit in Register STAR.
D2	SPSTOPN	Status/Space Stop Notify: This bit is used to enable the SPSTOP bit in Register STAR.
D3	CMDEN	Command Error Notify: This bit is used to enable the CMDE bit in Register STAR.
D4	CWIN	Conditional Write Inhibit Notify: This bit is always Zero. CWI is always masked.
D5	CPEN	Control Bus Parity Error Notify: This bit is used to enable the CPE bit in Register STAR.
D6	BPEN	BMAC Device Parity Error Notify: This bit is used to enable the BPE bit in Register STAR.
D7	ERRN	Error Notify: This bit is used to enable the ERR bit in Register STAR.

7.0 Control Information (Continued)

Service Attention Register (SAR)

The Service Attention Register (SAR) is used to present the attentions for the service functions. Each bit may be enabled by setting the corresponding bit in the State Notify Register.

This register is set to the value 0Fh upon reset.

Access Rules

Address	Read	Write
108h	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
RES	RES	RES	RES	ABR0	ABR1	LMOP	PTOP

Bit	Symbol	Description
D0	PTOP	<p>Pointer RAM Operation: This bit is cleared by the host to cause the MACSI device to transfer data between a Pointer RAM Register and a predefined mailbox location in memory. The Pointer RAM Control and Address Register contains the Pointer RAM Register address and determines the direction of the transfer (read or write). The memory address is defined via the Mailbox Address Register. This bit is set by the MACSI device after it performs the data transfer.</p> <p>While PTOP = 0, the host must not alter the Pointer RAM Address and Control Register or the Mailbox Address Register.</p>
D1	LMOP	<p>Limit RAM Operation: This bit is cleared by the host to cause the MACSI device to transfer data between a Limit RAM Register and the Limit Data and Limit Address Registers. The Limit Address Register contains the Limit RAM Register address and determines the direction of the transfer (read and write). This bit is set by the MACSI device after it performs the data transfer.</p> <p>While LMOP = 0, the host must not alter either the Limit Address or Limit Data Register.</p>
D2	ABR1	<p>Abort Request RCHN1: This bit is cleared by the host to abort a Request on RCHN1. This bit is set by the MACSI device when RQABORT ends a request on RCHN1. The host may write a 1 to this bit, which may or may not prevent the request from being aborted. When this bit is cleared by the host, the USR1 bit in the Request Attention Register is set and further processing on RCHN1 is halted.</p>
D3	ABR0	<p>Abort Request RCHN0: This bit is cleared by the host to abort a Request on RCHN0. This bit is set by the MACSI device when RQABORT ends a request on RCHN0. The host may write a 1 to this bit, which may or may not prevent the request from being aborted. When this bit is cleared by the host, the USR0 bit in the Request Attention Register is set and further processing on RCHN0 is halted.</p>
D7–D4	RES	Reserved

7.0 Control Information (Continued)

Service Notify Register (SNR)

The Service Notify Register (SNR) is used to enable attentions in the Service Attention Register (SAR). If a bit in Register SNR is set to One, the corresponding bit in Register SAR will be applied to the Master Attention Register, which can be used to generate an interrupt to the host.

All bits in this register are set to Zero upon reset.

7.0 Control Information (Continued)

No Space Attention Register (NSAR)

The No Space Attention Register (NSAR) presents the attentions generated when the CNF, PSP, or IDUD Queues run out of space. The host may set any attention bit to cause an attention for test purposes only, though this should not be done during normal operation.

The No Data Space attentions are set and cleared by the MACSI device automatically. The No Status Space attentions are set by the MACSI device, and must be cleared by the host.

Upon reset this register is set to 0xff.

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
NSR0	NSR1	LDI0	NSI0	LDI1	NSI1	LDI2	NSI2

Bit	Symbol	Description
D0	NSI2	No Status Space on ICHN2: This bit is set by the MACSI device upon a Reset, or when an IDUD has been written to the next-to-last available entry in the Indicate Channel's IDUD Status Queue. When this occurs, the MACSI device stops copying on ICHN2 and the last IDUD is written with special status. This bit must be cleared by the host before the MACSI device will resume copying on this Channel. Note that this bit should only be cleared after the appropriate limit register has been updated to give the MACSI more status space.
D1	LDI2	Low Data Space on ICHN2: This bit is set by the MACSI device upon Reset, or when a PSP is prefetched from ICHN2's last PSP Queue location (as defined by the PSP Queue Limit Register). Note that the amount of warning is dependent on the length of the frame. There will always be one more page (4 kBytes) available for the MACSI device when this attention is generated. Another FDDI maximum-length frame (after the current one) will not fit in this space. If PSP fetching was stopped because there were no more PSP entries, fetching will resume automatically when the PSP Queue Limit Register is updated. This bit will be cleared automatically when the new PSP Descriptors are fetched. This bit should never be cleared directly by software. Clearing this bit can cause the MACSI device to fetch invalid PSP descriptors.
D2	NSI1	No Status Space on ICHN1: This bit is set by the MACSI device upon a Reset, or when an IDUD has been written to the next-to-last available entry in the Indicate Channel's IDUD Status Queue. When this occurs, the MACSI device stops copying on ICHN1 and the last IDUD is written with special status. This bit must be cleared by the host before the MACSI device will resume copying on this Channel. Note that this bit should only be cleared after the appropriate limit register has been updated to give the MACSI device more status space.
D3	LDI1	Low Data Space on ICHN1: This bit is set by the MACSI device upon Reset, or when a PSP is prefetched from ICHN1's last PSP Queue location (as defined by the PSP Queue Limit Register). Note that the amount of warning is dependent on the length of the frame. There will always be one more page (4 kBytes) available for the MACSI device when this attention is generated. Another FDDI maximum-length frame (after the current one) will not fit in this space. If PSP fetching was stopped because there were no more PSP entries, fetching will resume automatically when the PSP Queue Limit Register is updated. This bit will be cleared automatically when the new PSP Descriptors are fetched. This bit should never be cleared directly by software. Clearing this bit can cause the MACSI device to fetch invalid PSP descriptors.

7.0 Control Information (Continued)

Bit	Symbol	Description
D4	NSI0	No Status Space on ICHN0: This bit is set by the MACSI device upon a Reset, or when an IDUD has been written to the next-to-last available entry in the Indicate Channel's IDUD Status Queue. When this occurs, the MACSI device stops copying on ICHN0 and the last IDUD is written with special status. This bit must be cleared by the host before the MACSI device will resume copying on this Channel. Note that this bit should only be cleared after the appropriate limit register has been updated to give the MACSI device more status space.
D5	LDI0	Low Data Space on ICHN0: This bit is set by the MACSI device upon Reset, or when a PSP is prefetched from ICHN0's last PSP Queue location (as defined by the PSP Queue Limit Register). Note that the amount of warning is dependent on the length of the frame. There will always be one more page (4 kBytes) available for the MACSI device when this attention is generated. Another FDDI maximum-length frame (after the current one) will not fit in this space. If PSP fetching was stopped because there were no more PSP entries, fetching will resume automatically when the PSP Queue Limit Register is updated. This bit will be cleared automatically when the new PSP Descriptors are fetched. This bit should never be cleared directly by software. Clearing this bit can cause the MACSI device to fetch invalid PSP descriptors.
D6	NSR1	No Status Space on RCHN1: This bit is set by the MACSI device upon a Reset, or when it has written a CNF Descriptor to the next-to-last Queue location. Due to internal pipelining, the MACSI device may write up to two more CNFs to the Queue after this attention is generated. Thus the Host must set the CNF Queue Limit Register to be one less than the available space in the Queue. This bit (as well as the USR attention bit) must be cleared by the Host before the MACSI device will continue to process requests on RCHN1. Note that this bit should only be cleared after the appropriate limit register has been updated to give the MACSI device more status space.
D7	NSR0	No Status Space on RCHN0: This bit is set by the MACSI device upon Reset, or when it has been written a CNF Descriptor to the next-to-last Queue location. Due to internal pipelining, the MACSI device may write up to two more CNFs to the Queue after this attention is generated. Thus the Host must set the CNF Queue Limit Register to be one less than the available space in the Queue. This bit (as well as the USR attention bit) must be cleared by the Host before the MACSI device will continue to process requests on RCHN0. Note that this bit should only be cleared after the appropriate limit register has been updated to give the MACSI device more status space.

7.0 Control Information (Continued)

No Space Notify Register (NSNR)

The No Space Notify Register (NSNR) is used to enable attentions in the No Space Attention Register (NSAR). If a bit in Register NSNR is set to One, the corresponding bit in Register NSAR will be applied to the Master Attention Register, which can be used to generate an interrupt to the host.

All bits in this register are set to Zero upon reset.

Bit	Symbol	Description
D7–D0	LDR7–0	Limit RAM Data Bit 7–0: This bit contains the least-significant data bit read or written from or to a Limit RAM Register in an LMOP service function. Bit LDR7 is a “don’t care” when using small (1 kByte) queues.

7.0 Control Information (Continued)

Request Attention Register (RAR)

The Request Attention Register (RAR) is used to present exception, breakpoint, request complete, and unserviceable request attentions generated by each Request Channel. Each bit may be enabled by setting the corresponding bit in the Request Notify Register.

All bits in this register are set to Zero upon reset.

Access Rules

Address	Read	Write
10Eh	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
USRR0	RCMR0	EXCR0	BRKR0	USRR1	RCMR1	EXCR1	BRKR1

Bit	Symbol	Description
D0	BRKR1	Breakpoint on RCHN1: Is set by the MACSI device when a CNF Descriptor is written on RCHN1. No action is taken by the MACSI device if the host sets this bit.
D1	EXCR1	Exception on RCHN1: Is set by the MACSI device when an exception occurs on RCHN1. An exception condition consists of one of the following events: ABus Error, Consistency Failure (REQ or ODUD), BMAC MAC Reset, Timeout (TRT expires), BMAC abort (MAC frame received or FC/Request Class inconsistency), RINGOP change, host abort (via SAR register), FIFO underrun, or confirmation exception (for full Confirmation). No action is taken by the MACSI device if the host sets this bit. This bit indicates that a request on RCHN1 did not complete normally. This implies that an exception event occurred or that the Request is improperly formed. The corresponding Confirmation (CNF) Descriptor will give more status about the failure. The additional information in the CNF descriptor should be used to make a decision about the severity of the error. If the exception was caused by an ABus error, the RQSTOP will also be set.
D2	RCMR1	Request Complete on RCHN1: Is set by the MACSI device when it has completed processing a Request object on RCHN1 (note that the MACSI may set this bit before writing the CNF descriptor to the CNF queue). This completion may be a normal completion where a request object was transmitted without error. It may also be an abnormal completion due to one of the exception conditions listed above in EXCR1. No action is taken if the Host sets this bit.
D3	USRR1	Unserviceable Request on RCHN1: Is set by the MACSI device when a Request cannot be processed on RCHN1. This occurs when the Request Class is inappropriate for the current ring state (e.g., Asynchronous transmission while RINGOP = 0), or when there is no CNF status space, or when the host aborts a request by clearing the ABR bit in the Service Attention Register. While this bit is set, no requests will be processed on RCHN1. The host must clear this bit to resume request processing. If the USRR1 was set due to lack of CNF space, this condition must be corrected by giving the MACSI device more CNF space before restarting the channel. If it was due to a request class/RINGOP incompatibility, then the reason for the incompatibility must be resolved.
D4	BRKR0	Breakpoint on RCHN0: Is set by the MACSI device when a CNF Descriptor is written on RCHN0. No action is taken by the MACSI device if the host sets this bit.

7.0 Control Information (Continued)

Bit	Symbol	Description
D5	EXCR0	<p>Exception on RCHN0: This bit is set by the MACSI device when an exception occurs on RCHN0. An exception condition consists of one of the following events: ABus Error, Consistency Failure (REQ or ODUD), BMAC MAC Reset, Timeout (TRT expires), BMAC abort (MAC frame received or FC/Request Class inconsistency), RINGOP change, host abort (via SAR register), FIFO underrun, or confirmation exception (for full Confirmation). No action is taken by the MACSI device if the host sets this bit.</p> <p>This bit indicates that a request on RCHN0 did not complete normally. This implies that an exception event occurred or that the Request is improperly formed. The corresponding Confirmation (CNF) Descriptor will give more status about the failure. The additional information in the CNF descriptor should be used to make a decision about the severity of the error. If the exception was caused by an ABus error, the RQSTOP will also be set.</p>
D6	RCMR0	<p>Request Complete on RCHN0: Is set by the MACSI device when it has completed processing a Request object on RCHN0. This completion may be a normal completion where a request object was transmitted without error. It may also be an abnormal completion due to one of the exception conditions listed above in EXCR0. This bit, (together with the Breakpoint bit BRKR0) indicates that there are CNF descriptors to be processed. No action is taken if the Host sets this bit.</p>
D7	USRR0	<p>Unserviceable Request on RCHN0: This bit is set by the MACSI device when a Request cannot be processed on RCHN0. This occurs when the Request Class is inappropriate for the current ring state (e.g., Asynchronous transmission while RINGOP = 0), or when there is no CNF status space, or when the host aborts a request by clearing the ABR bit in the Service Attention Register. While this bit is set, no requests will be processed on RCHN0.</p> <p>The host must clear this bit to resume request processing. If the USRR0 was set due to lack of CNF space, this condition must be corrected by giving the MACSI device more CNF space before restarting the channel. If it was due to a request class/RINGOP incompatibility, then the reason for the incompatibility must be resolved.</p>

7.0 Control Information (Continued)

Request Notify Register (RNR)

The Request Notify Register (RNR) is used to enable attentions in the Request Attention Register (RAR). If a bit in Register RNR is set to One, the corresponding bit in Register RAR will be applied to the Master Attention Register, which can be used to generate an interrupt to the host.

All bits in this register are set to Zero upon reset.

D3	USRR1N	Unserviceable Request on RCHN1 Notify: This bit is used to enable the USRR1 bit in Register RAR.
D4	BRKR0N	Breakpoint on RCHN0 Notify: This bit is used to enable the BRKR0 bit in Register RAR.
D5	EXCR0N	Exception on RCHN0 Notify: This bit is used to enable the EXCR0 bit in Register RAR.
D6	RCMR0N	Request Complete on RCHN0 Notify: This bit is used to enable the RCMR0 bit in Register RAR.
D7	USRR0N	Unserviceable Request on RCHN0 Notify: This bit is used to enable the USRR0 bit in Register RAR.

7.0 Control Information (Continued)

Request Channel 0 and 1 Configuration Registers 0 (R0CR0 and R1CR0)

The two Request Configuration Registers 0 (R0CR0 and R1CR0) are programmed with operational parameters for each of the Request Channels. Additional Request Channel parameters are configured in Request Configuration Registers 1. These registers may only be altered between Requests, i.e., while the particular Request Channel does not have a Request loaded.

These registers are not altered upon reset.

Access Rules

Address	Read	Write
110–111h	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
TT1	TT0	PRE	HLD	FCT	SAT	VST	FCS

Bit	Symbol	Description
D0	FCS	Frame Check Sequence Disable: When this bit is set, the MACSI device asserts the FCST signal throughout the request. This drives the Ring Engine FCST signal. This bit is used to program the Ring Engine (MAC) not to concatenate its generated FCS to the transmitted frame. The Valid FCS bit in the Expected Frame Status Register independently determines whether a frame needs a valid FCS to meet the matching frame criteria.
D1	VST	Void Stripping: When this bit is set, the MACSI device asserts the STRIP signal out throughout the request. This drives the Ring Engine STRIP (Void Strip) signal. The STRIP signal may also drive the Ring Engine SAT signal, depending on the state of the BOSEL bit. See “MAC Mode Register 2 (MCMR2)”.
D2	SAT	Source Address Transparency: When this bit is set, the MACSI device asserts the SAT output signal throughout the request. This drives the Ring Engine SAIGT signal. It may optionally drive the SAT signal depending upon the setting of the BOSEL bit. See “MAC Mode Register 2 (MCMR2)”. When SAT is set, Full Confirmation requires the use of the EM (External SA Match) signal.
D3	FCT	Frame Control Transparency: When this bit is set, the FC will be sourced from the ODU (not the REQ.First or REQ.Only Descriptor). When Full Confirmation is enabled and FCT = 0, all bits of the FC in returning frames must match the FC field in the REQ Descriptor; if FCT = 1, only the C, L and r bits must match. Note that since the MACSI device decodes the REQ.F Descriptor FC field to determine whether to assert RQCLM/RQBCN, FC transparency may be used to send Beacons or Claims in any ring non-operational state, as long as the FC in the REQ Descriptor is not set to Beacon or Claim. By programming a Beacon or Claim FC in the REQ Descriptor, then using FC transparency, any type of frame may be transmitted in the Beacon or Claim state.
D4	HLD	Hold: When this bit is set, the MACSI device will not end a service opportunity until the Request is complete. When this bit is Zero, the MACSI device ends the service opportunity on the Request Channel when all of the following conditions are met: <ol style="list-style-type: none"> 1. There is no valid request active on the Request Channel. 2. The service class is non-immediate. 3. There is no data in the FIFO. 4. There is no valid REQ fetched by the MACSI device. This bit also affects Prestaging on RCHN1 (Request Channel 1). When HLD = 0, prestaging is enabled on RCHN1, regardless of the state of the PRE bit (except for Immediate service classes). When HLD = 1, prestaging is determined by the PRE bit. This option can potentially waste ring bandwidth, but may be required (particularly on RCHN0, Request Channel 0) if a guaranteed service time is required. When using the Repeat option, HLD is required for small frames. If HLD is not used, the other Request Channel will be checked for service before releasing the token between frames. This may not be the desired action, particularly if there is a request on RCHN1 that needs servicing after the completion of RCHN0's Repeated Request.

7.0 Control Information (Continued)

Bit	Symbol	Description															
D5	PRE	<p>Preempt/Prestage: When this bit is set, preemption is enabled for RCHN0, and prestaging is enabled for RCHN1 (prestaging is always enabled for RCHN0). When this bit is Zero, preemption is disabled and Prestaging is enabled on the RCHN0.</p> <p>When preemption is enabled, RCHN0 preempts a (non-committed) frame of RCHN1 already in the FIFO, causing it to be purged and refetched after RCHN0's request has been serviced. When the Request Machine servicing on RCHN1 and a request on RCHN0 becomes active, if preemption is enabled on RCHN0, the Request Machine will finish transmitting the current frame on RCHN1, then release the token and move back to the start state. This has the effect of reprioritization of the Request Channels, thus ensuring that frames on RCHN0 are transmitted at the next service opportunity. When RCHN0 has been serviced, transmission will continue on RCHN1 with no loss of data.</p> <p>When prestaging is enabled, the next frame for RCHN1 is staged (ODUs are loaded into the FIFO before the token arrives). If prestaging is not enabled, the Request Machine waits until the token is captured before staging the first frame. Once the token is captured, the Request Machine begins fetching data, and when the FIFO threshold has been reached, transmits the data on the Request Channel. For requests with an Immediate service class, prestaging is not applicable.</p> <p>When this bit is Zero, preemption is disabled for RCHN0, and request on RCHN1 will not be prestaged unless the HLD bit is Zero, in which case RCHN1 will prestage data regardless of the setting of the PRE bit.</p> <p>Note that when prestaging is not enabled on RCHN1, data is not staged until the token is captured. Since there is no data in the FIFO (if there is no active request on RCHN0), the MACSI device will immediately release the token if the HLD option is not set.</p>															
D7–D6	TT1–0	<p>Transmit Threshold: These bits in conjunction with the EFT bit, determine the threshold on the output data FIFO before the MACSI device requests transmission. See “Request Channel 0 and 1 Configuration Registers 1 (R0CR1 and R1CR1)”.</p> <table border="1"> <thead> <tr> <th>TT1</th> <th>TT0</th> <th>Threshold Value</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>8 Words or 512 Words</td> </tr> <tr> <td>0</td> <td>1</td> <td>16 Words or Reserved</td> </tr> <tr> <td>1</td> <td>0</td> <td>128 Words or Reserved</td> </tr> <tr> <td>1</td> <td>1</td> <td>256 Words or End of Frame</td> </tr> </tbody> </table>	TT1	TT0	Threshold Value	0	0	8 Words or 512 Words	0	1	16 Words or Reserved	1	0	128 Words or Reserved	1	1	256 Words or End of Frame
TT1	TT0	Threshold Value															
0	0	8 Words or 512 Words															
0	1	16 Words or Reserved															
1	0	128 Words or Reserved

7.0 Control Information (Continued)

Request Channel 0 and 1 Expected Frame Status Registers (R0EFSR and R1EFSR)

The Expected Frame Status Registers (R0EFSR and R1EFSR) define the matching criteria used for Full Confirmation of returning frames on each Request Channel. A returning frame must meet the programmed criteria to be counted as a matching returning frame on each Request Channel. A returning frame must meet the programmed criteria to be counted as a matching returning frame.

These registers are not altered upon reset.

7.0 Control Information (Continued)

Indicate Attention Register (IAR)

The Indicate Attention Register (IAR) is used to present exception and breakpoint attentions generated by each Indicate Channel. An Attention bit is set by hardware when an exception or breakpoint occurs on the corresponding Indicate Channel. Each bit may be enabled by setting the corresponding bit in the Indicate Notify Register.

All bits in this register are set to Zero upon reset.

Access Rules

Address	Read	Write
114h	Always	Conditional

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
RES	RES	EXCI0	BRKI0	EXCI1	BRKI1	EXCI2	BRKI2

Bit	Symbol	Description
D0	BRKI2	Breakpoint on ICHN2: This bit is set when a breakpoint is detected on Indicate Channel 2. No action is taken if the host sets this bit.
D1	EXCI2	Exception on ICHN2: While this bit is set, copying is disabled on ICHN2. This bit is set by the MACSI device when an exception occurs on Indicate Channel 2. An exception consists of an ABus error during an IDU or IDUD write for ICNH2. It may be set by the host to disable copying on ICHN2, which is convenient when updating the Indicate Header Length and Indicate Threshold register. When this bit is set by the device it signifies that the last frame received on this channel had an ABus error. It is the last frame because the setting of this bit disables further copying on this channel. The last frame should be discarded.
D2	BRKI1	Breakpoint on ICHN1: This bit is set when a breakpoint is detected on Indicate Channel 1. No action is taken if the host sets this bit.
D3	EXCI1	Exception on ICHN1: While this bit is set, copying is disabled on ICHN1. This bit is set by the MACSI device when an exception occurs on Indicate Channel 1. An exception consists of an ABus error during an IDU or IDUD write for ICNH1. It may be set by the host to disable copying on ICHN1, which is convenient when updating the Indicate Header Length and Indicate Threshold register. When this bit is set by the device it signifies that the last frame received on this channel had an ABus error. It is the last frame because the setting of this bit disables further copying on this channel. The last frame should be discarded.
D4	BRKI0	Breakpoint on ICHN0: This bit is set when a breakpoint is detected on ICHN0. No action is taken if the host sets this bit. The User must set IMCR.BOS to use the BRKI0 breakpoint.
D5	EXCI0	Exception on ICHN0: While this bit is set, copying is disabled on ICHN0. This bit is set by the MACSI device when an exception occurs on Indicate Channel 0. An exception consists of an ABus error during an IDU or IDUD write for ICNH0. It may be set by the host to disable copying on ICHN0. When this bit is set by the device it signifies that the last frame received on this channel had an ABus error. It is the last frame because the setting of this bit disables further copying on this channel. The last frame should be discarded.
D7–D6	RES	Reserved

7.0 Control Information (Continued)

Indicate Notify Register (INR)

The Indicate Notify Register (INR) is used to enable attentions in the Indicate Attention Register (IAR). If a bit in Register INR is set to One, the corresponding bit in Register IAR will be applied to the Master Attention Register, which can be used to generate an interrupt to the host.

All bits in this register are set to Zero upon reset.

Bit	Symbol	Description
D0	BRK2N	Breakpoint on ICHN2 Notify: This bit is used to enable the BRK2 bit in Register IAR.
D1	EXC2N	Exception on ICHN2 Notify: This bit is used to enable the EXC2 bit in Register IAR.
D2	BRK1N	Breakpoint on ICHN1 Notify: This bit is used to enable the BRK1 bit in Register IAR.
D3	EXC1N	Exception on ICHN1 Notify: This bit is used to enable the EXC1 bit in Register IAR.
D4	BRK0N	Breakpoint on ICHN0 Notify: This bit is used to enable the BRK0 bit in Register IAR.
D5	EXC0N	Exception on ICHN0 Notify: This bit is used to enable the EXC0 bit in Register IAR.
D7–D6	RES	Reserved

Indicate Threshold Register (ITR)

The Indicate Threshold Register (ITR) specifies the maximum number of frames that can be received on Indicate Channel 1 or Indicate Channel 2 before an attention will be generated. This register may be written only when the INSTOP bit in the State Attention Register is set, or when the Indicate Channel's corresponding EXC bit in the Indicate Attention Register is set.

This register is not altered upon reset.

Access Rules

Address	Read	Write
116h	Always	INSTOP Mode or EXC = 1 Only

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
THR7	THR6	THR5	THR4	THR3	THR2	THR1	THR0

Bit	Symbol	Description
D7–D0	THR7–0	Threshold Data Bits 7–0: The value programmed in this register is loaded into an internal counter every time the Indicate Channel changes. Each valid frame copied on the current Channel decrements the counter. When the counter reaches Zero, a status breakpoint attention is generated (i.e., the Channel's BRK bit in the Indicate Attention Register is set) if the Channel's Breakpoint on Threshold (BOT) bit in the Indicate Mode Register is set. Loading the Indicate Threshold Register with Zero generates a breakpoint after 256 consecutive frames are received on any one Indicate Channel.

7.0 Control Information (Continued)

Indicate Mode Configuration Register (IMCR)

The Indicate Mode Configuration Register (IMCR) defines configuration options for all three indicate Channels, including the sort mode, frame filtering, and status breakpoints.

This register may be written only when the INSTOP bit in the State Attention Register is set. It may be written with its current value any time, which is useful for one-shot sampling.

This register is not altered upon reset.

Access Rules

Address	Read	Write
117h	Always	INSTOP Mode Only

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
SM1	SM0	SKIP	FPP	BOT2	BOT1	BOB	BOS

Bit	Symbol	Description
D0	BOS	Breakpoint on Service Opportunity: Enables the end of a service opportunity to generate an Indicate breakpoint attention (i.e., set the Channel's BRK bit in the Indicate Attention Register). Service opportunities include receipt of a Token, a MAC Frame, or a ring operational change following some copied frames. This bit should be set to 1 if BRKI0 will be used.
D1	BOB	Breakpoint on Burst: Enables the end of a burst to generate an Indicate breakpoint attention (i.e., set the Channel's BRK bit in the Indicate Attention Register). End of burst includes Channel change, DA change, SA change, or MAC INFO change. A Channel change is detected from the FC field of valid, copied frames. A DA change is detected when a frame's DA field changes from this station's address to any other. An SA change is detected when a frame's SA field is not the same as the previous one. A MAC INFO change occurs when a MAC frame does not have the identical first four bytes of INFO as the previous frame. This breakpoint always sets the BRK bit (i.e., this breakpoint is always enabled).
D2	BOT1	Breakpoint on Threshold for ICHN1: Enables the value in the Indicate Threshold Register to be used to generate an Indicate breakpoint attention on Indicate Channel 1 (i.e., set the BRK1 bit in the Indicate Attention Register).
D3	BOT2	Breakpoint on Threshold for ICHN2: Enables the value in the Indicate Threshold Register to be used to generate an Indicate breakpoint attention on Indicate Channel 2 (i.e., set the BRK2 bit in the Indicate Attention Register).
D4	FPP	Frame-per-Page: This bit controls how received frames are packed into the Pool Space Pages which are provided via the PSP Descriptors. When this bit is reset, the MACSI device assembles multiple frames into a single page of Pool Space when possible (i.e., the frames are smaller than the 4 kByte page size). When this bit is set, the MACSI device will force a page break and fetch a new PSP for each frame received. This guarantees that no page will contain more than one frame. When FPP is set, Frame packing can be re-enabled on individual channels. See "Address Configuration Register (ACR)". This mode is useful for systems where received frames are not processed in order of receipt. This is because space reclamation is greatly simplified. A side affect of this mode is that no frame will span more than two pages (i.e., a frame will have at most two IDUDs).
D5	SKIP	Skip Enable: Enables filtering on Indicate Channel 0 when the Copy Control field for ICHN0 in the Indicate Configuration Register is set to 01 or 10. When this bit is set, only the unique MAC frames received on Indicate Channel 0 will be copied to memory (i.e., those having an FC field or first four bytes of the Information field that differs from the previous frame). When this bit is 0, the MACSI will copy all MAC frames that meet the Copy Criteria. When this bit changes from a 0 to a 1, the MACSI will copy the next MAC frame, even if it is the same as the previous frame. Note that the "Promiscuous" Copy Mode overrides this SKIP mode (when the User selects Promiscuous copy and the SKIP mode, the MACSI will copy all MAC frames).

7.0 Control Information (Continued)

Bit	Symbol	Description																				
D7–D6	SM1–0	<p>Sort Mode: These bits determine how the MACSI device sorts Indicate data onto Indicate Channels 1 and 2.</p> <table border="1"> <thead> <tr> <th>SM1</th> <th>SM0</th> <th>ICHN2</th> <th>ICHN1</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Asynchronous</td> <td>Synchronous</td> </tr> <tr> <td>0</td> <td>1</td> <td>External</td> <td>Internal</td> </tr> <tr> <td>1</td> <td>0</td> <td>Info</td> <td>Header</td> </tr> <tr> <td>1</td> <td>1</td> <td>Low Priority</td> <td>High Priority</td> </tr> </tbody> </table> <p>The Synchronous/Asynchronous Sort Mode is intended for use in end-stations or applications using synchronous transmission.</p> <p>The Internal/External Sorting Mode is intended for bridging or monitoring applications. MAC/SMT frames matching the internal Ring Engine (MAC) address are sorted onto ICHN0, and all other frames matching the Ring Engine's internal address (short or long) are sorted onto ICHN1. All frames matching the external address (frames requiring bridging) are sorted onto ICHN2. This sorting mode uses the EM, ECOPI, and ECIP input signals with external address matching circuitry. See the section on External address matching for a full description of the timing required on these signals (Section 6.3). Promiscuous mode on ICHN2 does not require any external matching logic to copy frames.</p> <p>The Header/Info Sort Mode is intended for high performance protocol processing. MAC/SMT frames are sorted onto ICHN0, while all other frames are sorted onto ICHN1 and ICHN2. Frame bytes from the FC up to the programmed header length are copied onto ICHN1. The remaining bytes(info) are copied onto ICHN2. Only one stream of IDUDs is produced (on ICHN1), but both Indicate Channel's PSP queues are used for space (i.e., PSPs from ICHN1 for header space, and PSPs from ICHN2 for info space). Frames may comprise a header only, or a header + info. For frames with info, multi-part IDUD objects are produced. For multi-part IDUDs, the Indicate Status field in the IDUD is used to determine which part of the IDUD object points to the end of the header. The remainder of the IDUD is used to determine which part of the IDUD object points to the end of the header. The remainder of the IDUD object points to the Info. If Pool Space is only declared for ICNH1, then only the Headers will be written to memory. This is useful for protocol monitor applications.</p> <p>For example, if page crosses occur while writing the header and while writing out the Info, the MACSI device will generate a four part IDUD object (IDUD.First, IDUD.Middle, IDUD.Middle, IDUD.Last). The IDUD.First will have a status of "page cross". The first IDUD. Middle will have a status of "end of header". The next IDUD.Middle will have a status of "page cross". The IDUD.Last will have an "end of frame" status.</p> <p>The High Priority/Low Priority Sort Mode is intended for end stations using two priority levels of asynchronous transmission. The priority is determined by the most-significant z-bit of the FC (zzz = 0xx = low-priority; zzz = 1xx = high priority). Synchronous frames are sorted onto ICHN1 and MAC/SMT frames are sorted onto ICHN0.</p>	SM1	SM0	ICHN2	ICHN1	0	0	Asynchronous	Synchronous	0	1	External	Internal	1	0	Info	Header	1	1	Low Priority	High Priority
SM1	SM0	ICHN2	ICHN1																			
0	0	Asynchronous	Synchronous																			
0	1	External	Internal																			
1	0	Info	Header																			
1	1	Low Priority	High Priority

7.0 Control Information (Continued)

Indicate Header Length Register (IHLR)

The Indicate Header Length Register (IHLR) defines the length (in words) of the frame header, for use with the Header/Info Sort Mode.

The Indicate Header Length Register must be initialized before setting the Sort Mode in Header/Info. This register may be changed while the INSTOP bit in the State Attention Register or the EXC bit in the Indicate Attention Register is set.

This register is not altered upon reset.

Access Rules

Address	Read	Write
119h	Always	INSTOP Mode or EXC = 1 Only

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
HL7	HL6	HL5	HL4	HL3	HL2	HL1	HL0

Bit	Symbol	Description
D7–D0	HL7–0	Header Length: Specifies the length (in words) of the frame header, for use with the Header/Info Sort Mode. The frame FC is written as a separate word, and thus counts as one word. For example, to split after eight bytes of FDDI INFO in a frame with long addresses, this register is programmed with the value 06 (1 word FC, 1.5 DA, 1.5 SA, 2HDR_DATA). IHLR must not be loaded with a value less than 4. If it is, the MACSI device sets the Command Error (CMDE) and Indicate Stop (INSTOP) attentions. This Register only affects the Header/Info sort mode.

7.0 Control Information (Continued)

Address Configuration Register (ACR)

This register contains bits for configuring the address swapping logic.

All bits in this register are set to Zero upon reset.

Access Rules

Address	Read	Write
11Ah	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
PCKI2	PCKI1	PCKI0	RSWP1	RSWP0	ISWP2	ISWP1	ISWP0

Bit	Symbol	Description
D0	ISWP0	Indicate Swap 0: This bit controls the address swapping logic for Indicate Channel 0 (ICHN0). If this bit is reset, no address swapping takes place. If this bit is set, both Destination (DA) and Source address (SA) fields are swapped from FDDI bit ordering to canonical bit ordering. This involves a bit reversal within each byte.
D1	ISWP1	Indicate Swap 1: This bit controls the address swapping logic for Indicate Channel 1 (ICHN1). If this bit is reset, no address swapping takes place. If this bit is set, both Destination (DA) and Source address (SA) fields are swapped from FDDI bit ordering to canonical bit ordering. This involves a bit reversal within each byte.
D2	ISWP2	Indicate Swap 2: This bit controls the address swapping logic for Indicate Channel 2 (ICHN2). If this bit is reset, no address swapping takes place. If this bit is set, both Destination (DA) and Source address (SA) fields are swapped from FDDI bit ordering to canonical bit ordering. This involves a bit reversal within each byte.
D3	RSWP0	Request Swap 0: This bit controls the address swapping logic for Request Channel 0 (RCHN0). If this bit is reset, no address swapping takes place. If this bit is set, both Destination (DA) and Source address (SA) fields are swapped from canonical bit ordering to FDDI bit ordering. This involves a bit reversal within each byte.
D4	RSWP1	Request Swap 1: This bit controls the address swapping logic for Request Channel 1 (RCHN1). If this bit is reset, no address swapping takes place. If this bit is set, both Destination (DA) and Source address (SA) fields are swapped from canonical bit ordering to FDDI bit ordering. This involves a bit reversal within each byte.
D5	PCKI0	Pack Frames on ICHN0: This bit controls the packing of Frames into Pool Space Pages for Indicate Channel 0 (ICHN0). When the Frame-Per-Page (FPP) bit is set (see "Indicate Mode Configuration Register (IMR)"), the MACSI device will cause a page break and start each new Frame in a new Pool Space Buffer. Setting the PCKI0 bit selectively disables the Frame-Per-Page mode for ICHN0. If the FPP bit is zero, this PCKI0 bit has no effect.
D6	PCKI1	Pack Frames on ICHN1: This bit controls the packing of Frames into Pool Space Pages for Indicate Channel 1 (ICHN1). When the Frame-Per-Page (FPP) bit is set (see "Indicate Mode Configuration Register (IMR)"), the MACSI device will cause a page break and start each new Frame in a new Pool Space Buffer. Setting the PCKI1 bit selectively disables the Frame-Per-Page mode for ICHN1. If the FPP bit is zero, this PCKI1 bit has no effect.
D7	PCKI2	Pack Frames on ICHN2: This bit controls the packing of Frames into Pool Space Pages for Indicate Channel 2 (ICHN2). When the Frame-Per-Page (FPP) bit is set (see "Indicate Mode Configuration Register (IMR)"), the MACSI device will cause a page break and start each new Frame in a new Pool Space Buffer. Setting the PCKI2 bit selectively disables the Frame-Per-Page mode for ICHN2. If the FPP bit is zero, this PCKI2 bit has no effect.

7.0 Control Information (Continued)

Request Channel 0 and 1 Configuration Registers 1 (R0CR1 and R1CR1)

The two Request Configuration Registers 1 (R0CR1 and R1CR1) are programmed with additional operational parameters for each of the Request Channels. Other Request Channel parameters are configured in Request Configuration Registers 0. These registers may only be altered between Requests, i.e., while the particular Request Channel does not have a Request loaded.

All bits in these registers are set to Zero upon reset.

11Fh	Always	Always

Register Bits

D7	D6	D5	D4	D3	D2	D1	D0
CMP7	CMP6	CMP5	CMP4	CMP3	CMP2	CMP1	CMP0

Bit	Symbol	Description
D7–D0	CMP7–CMP0	Compare: These bits are compared to bits D7–D0 of the accessed System Interface register. Only the bits in the System Interface Attention Register that have the same current value as the corresponding bit in the Compare register will be updated with the new value.

7.8 POINTER RAM REGISTERS

Pointer RAM Registers contain pointers to all data and Descriptors manipulated by the MACSI device, namely, Input and Output Data Units, Input and Output Data Unit Descriptors, Request Descriptors, Confirmation Messages, and Pool Space Descriptors. Pointer RAM Registers are shown in *Figure 7-3*.

7.9 LIMIT RAM REGISTERS

The Limit RAM Registers are used by both the Indicate and Request machines. Limit RAM Registers contain data values that define how far the MACSI device may advance in each of its ten queues. The Limit RAM Registers do **not** define the wrap point for each queue which is fixed at either 1 kByte or 4 kBytes. Limit RAM Registers are shown in *Figure 7-4*.

7.10 DESCRIPTORS

Descriptors are used to observe and control the operation of the MACSI device. They contain address, status, and control information about Indicate and Request operations. Descriptors are stored in lists and wrap-around queues in

memory external to the MACSI device and accessed by the MACSI device via the ABus. Descriptors include the following: Input Data Unit Descriptors (IDUDs) specify the location, size, part, and status information for Input Data Units. Output Data Unit Descriptors (ODUDs) specify the location and size of Output Data Units. For multi-ODUD frames, they also specify which part of the frame is pointed to by the ODUD. Pool Space Descriptors (PSPs) describe the location and size of a region of memory space available for writing Indicate data. Request Descriptors (REQs) describe the location of a stream of Output Data Unit Descriptors and contain operational parameters. Confirmation Status Messages (CNFs) describe the result of a Request operation.

7.11 OPERATING RULES

Multi-Byte Register Ordering

When referring to multi-byte fields, byte 0 is always the most significant byte. When referring to bits within a byte, bit 7 is the most significant bit and bit 0 is the least significant bit. When referring to the contents of a byte, the most significant bit is always referred to first.

7.0 Control Information (Continued)

7.12 POINTER RAM REGISTER DESCRIPTIONS

The Pointer RAM Register set contains 32, 28-bit registers. Registers 23 through 31 are reserved, and user access of these locations produces undefined results. Pointer RAM Registers are read and written by the host using the Pointer RAM Operation (PTOP) service function and are accessed directly by MACSI device hardware during Indicate and Request operations. After initialization, the Pointer RAM Registers are maintained by the MACSI device and do not require host intervention.

During Indicate and Request operations, Pointer RAM registers are used as addresses for ABus accesses of data and Descriptors, i.e., the subchannel addresses for loads (reads) of streams of PSPs, ODUs, ODUDs, and REQs, and for stores (writes) of streams of IDUs, IDUDs, and CNFs.

Pointer RAM Registers include the following:

ODU Pointer: Contains the address of an Output Data Unit. During Request operations, this register is loaded by the MACSI device from the Location Field of its Output Data Unit Descriptor.

ODUD List Pointer: Loaded by the MACSI device from the Location Field of the REQ Descriptor when it is read from memory. The address is incremented by the MACSI device as each ODUD is fetched from memory.

CNF Queue Pointer: Contains the current CNF Status Queue address. This register is written by the user after he has allocated space for the CNF Queue. During Request operations, this register is incremented by the MACSI device after each CNF is written to the CNF Queue.

REQ Queue Pointer: Initialized by the host with the start address of the REQ Descriptor Queue after the Queue has been initialized. During Request operations, the address is incremented by the MACSI device as each REQ is fetched.

IDU Pointer: Written by the MACSI device with the Location Field of the PSP Descriptor when it is loaded from the PSP pre-fetch register.

IDUD Queue Pointer: Points to the Queue location where IDUDs will be stored. Written by the user after he has allocated space for the IDUD Status Queue. Incremented by the MACSI device as IDUDs are written to consecutive locations in the Queue.

PSP Queue Pointer Register: Points to the next available PSP. Initialized by the host with the start address of the PSP Queue. As each PSP is read from memory, this register is incremented.

Next PSP Register: Written by the MACSI device with the PSP fetched from the PSP Queue.

Indicate Shadow Register: Written by the MACSI device with the start address of the last IDU copied to memory.

Request Shadow Register: Written by the MACSI device with the address of the current ODUD.

See *Figure 7-3* for Summary including address and access rules.

7.13 LIMIT RAM REGISTER DESCRIPTIONS

The Limit RAM Register set contains 16, 9-bit registers. Registers 11 through 15 are reserved, and access of these locations produces undefined results.

The Limit RAM registers contain data values that define the limits of each of the ten queues maintained by the MACSI device.

Limit RAM Registers are read and written by the host using the Limit RAM Operation (LMOP) service function when the Status/Space Machine is in STOP Mode, and are read directly by MACSI device hardware during Indicate and Request operations.

Limit RAM Registers include the following:

REQ Queue Limit: Defines the last valid REQ written by the host.

CNF Queue Limit Register: Defines the last Queue location where a CNF may be written by the MACSI device. Due to pipelining, the MACSI device may write up to two CNFs after it detects a write to the next-to-last CNF entry (and generates a No Status Space Attention). For this reason, the host must always define the CNF queue limit to be one Descriptor less than the available space.

IDUD Queue Limit Register: Defines the last Queue location where an IDUD may be written by the MACSI device.

PSP Queue Limit: Defines the last valid PSP written by the host.

See *Figure 7-4* for Summary including address and access rules.

7.0 Control Information (Continued)

Input Data Unit Descriptor (IDUD)

Input Data Unit Descriptors (IDUDs) are generated on Indicate Channels to describe where the MACSI device wrote each frame part and to report status for the frame.

For multi-part IDUDs, intermediate status is written in each IDUD, and when a status event occurs, definitive status is written in the last IDUD.

A detailed description of the encodings of the Indicate Status bits is given in *Figure 7.5*.

31	30	29	28	27	24	23	16	15	14	13	12	0
IS		FRA			FRS			VC	RES		CNT	
F-L	RES		LOC									Word 1

Bit	Symbol	Description
Word 0		
D12–D0	CNT	Byte Count: Number of bytes in the IDU to which this IDUD points. This count includes the FDDI Frame Check Sequence (4 byte FCS) but it does not include the three FC pad bytes which are written.
D14–D13	RES	Reserved
D15	VC	VCOPY: Reflects the state of the internal VCOPY signal sent to the Ring Engine by the System Interface for this frame. 0: VCOPY was negated 1: VCOPY was asserted
D23–D16	FRS	Frame Status: This C, E, and A fields are valid only if the frame ended with an ED.
D17–D16	C	C Indicator: 00: none 01: R 10: S 11: T

Word 1																																																																																																																
D27–D0	LOC	Location: 28-bit memory address of the start of an IDU. For the first IDU of a frame, the address is of the fourth FC byte of the burst-aligned frame (i.e., bits [1:0] = 11). For subsequent IDUs, the address is of the first byte of the IDU (i.e., bits [1:0] = 00).																																																																																																														
D29–D28	RES	Reserved																																																																																																														
D31–D30	F-L	First/Last Tag: Identifies the IDU object part, i.e., Only, First, Middle, or Last. FL = 10 = First, FL = 00 = Middle, FL = 01 = Last, FL = 11=Only.																																																																																																														

7.0 Control Information (Continued)

NON-END FRAME STATUS

[0000]	Last IDUD of Queue, with a Page Cross: The last available location of the ICHN's IDUD queue was written. Since there was a page cross, there was more data to be written. Since there was no more IDUD space, the remaining data was not written. Note that this code will not be written in an IDUD.Middle, so that a Zero IS field with Zero F-L tags can be used by software as a null descriptor.
[0001]	Page Cross: Must be an IDUD.First or IDUD.Middle. This is part of a frame that filled up the remainder of the current page, requiring a new page for remainder of the data.
[0010]	Header End: This refers to the last IDU of the header portion of a frame.
[0011]	Page Cross and Header End: The occurrence of a page cross and header end.

NORMAL-END FRAME STATUS

[0100]	Intermediate: A frame ended normally, and there was no breakpoint.
[0101]	Burst Boundary: A frame ended normally, and there was a breakpoint because a burst boundary was detected.
[0110]	Threshold: The copied frame threshold counter was reached when this frame was copied, and the frame ended normally.
[0111]	Service Opportunity: This (normal end) frame was preceded by a token or MACRST, a MAC frame was received, or there was a ring-op change. Any of these events marks a burst boundary.

NO SPACE COPY ABORT

[1000]	Insufficient Data Space: Not all the frame was copied because there was insufficient data space. This code is only written in non-Header/Info Sort Mode.
[1001]	Insufficient Header Space: The frame copy was aborted because there was insufficient header space (in Header/Info Sort Mode0).
[1010]	Successful Header Copy, Frame Info Not Copied: There was sufficient space to copy the header, but insufficient data space to copy info, or insufficient IDU space (on ICHN2), or both. No info was copied.
[1011]	No Info Space: The frame's header was copied. When copying the data, there was insufficient data and/or IDU space.

ERROR

[1100]	FIFO Overrun: The Indicate FIFO had an overrun while copying this frame. This exception is caused when the memory interface does not allow the MACSI device to empty the data FIFO as quickly as it is being filled. This frame should not be processed because data has been lost.
[1101]	Bad Frame: This exception is caused when the incoming frame contains an invalid data length (too short or an odd number of symbols), or an invalid Frame Check Sequence (FCS). This implies that the frame was not a valid FDDI frame. Therefore, this frame should not be processed.
[1110]	Parity Error: This exception is caused when the MACSI device detects an internal parity error at the System Interface-Ring Engine interface (the MR.FLOW bit must be set to enable parity checking). This implies a data corruption error within the frame. Therefore, this frame should not be processed.
[1111]	Internal Error: This exception is caused when the MACSI device detects an internal hardware error (e.g. illegal state machine state), in the receive logic while receiving a frame. This implies that the frame data may have been corrupted. Therefore, this frame should not be processed. In addition, the MACSI device should be reset and reinitialized.

FIGURE 7-5. Indicate Status Field (IS) of IDU Descriptor

7.0 Control Information (Continued)

REQ Descriptor (REQ)

Request Descriptors (REQs) contain the part, byte address, and size of one or more Output Data Unit Descriptors. They also contain parameters and commands to the MACSI device associated with Request operations.

Multiple REQ Descriptors (parts) may be grouped as one Request Descriptor object by the host software, with the REQ.First defining the parameters for the entire Request object. Also multiple Output Data Unit Descriptors may be grouped contiguously, to be described by a single REQ Descriptor.

Each REQ part is fetched by the MACSI device from the Request Channel's REQ Descriptor Queue, using the REQ Queue Pointer Register. Each Request Channel processes one Request Object (REQ.Only or REQ.First to REQ.Last set), per service opportunity.

The MACSI device checks for the following inconsistencies when the REQ is loaded from memory:

1. REQ.First with invalid Confirmation Class (as shown in the *Figure 7-7*).
2. REQ.First with Request Class = 0.
3. REQ.First, when the previous REQ was not a REQ.Last or REQ.Only.
4. REQ which is not a REQ.First or REQ.Only when the previous REQ was a REQ.Last or a REQ.Only

When an inconsistency is detected, the MACSI device aborts the Request, and reports the exception in the Request Status field of the CNF Descriptor.

The encodings of the RQCLS and CNFCLS bits are described in more detail in *Figure 7-6* and *Figure 7-7* respectively.

31	30	29	28	27	24	23	16	15	12	11	8	7	0
RES	UID			SIZE			CNFCLS	RQCLS		FC			Word 0
F-L	RES	LOC											Word 1

Bit	Symbol	Description
Word 0		
D7–D0	FC	Frame Control: This specifies the Frame control field to be used unless FC transparency is enabled. This field is decoded to determine whether to assert RQCLM or RQBCN. This decoding is always active, i.e., regardless of frame control transparency. This field is also used for comparing received frames when confirming (without FC transparency).
D8–D11	RQCLS	Request/Release Class: This field encodes the Request Class for the entire Request object, and is thus only sampled on a REQ.First or REQ.Only. The field is asserted on the RQRCLS signals to the Ring Engine when requesting a token. If the Request Class is incompatible with the current ring state, the MACSI device sets the RCHN's USR bit in the Request Attention Register. The encoding of this field is shown in <i>Figure 7-6</i> .
D15–D12	CNFCLS	Confirmation Class: This field encodes the Confirmation Class for the entire Request object, and is only sampled on a REQ.First or REQ.Only. The encoding of this field is shown in <i>Figure 7-7</i> .
D12	E	End: Enables confirmation on completion of request. 0: CNFs on completion disabled. 1: CNFs on completion enabled.
D13	I	Intermediate: Enables Intermediate (at the end of each Service Opportunity) Confirmation. 0: Intermediate CNFs disabled. 1: Intermediate CNFs enabled.
D14	F	Full/Transmitter: Selects between Transmitter and Full Confirmation. 0: Transmitter confirm. 1: Full confirm.

7.0 Control Information (Continued)

Bit	Symbol	Description
Word 0 (Continued)		
D15–D12	CNFCLS	Confirmation Class: (Continued)
D15	R	<p>Repeat: Enables repeated transmission of the first frame of the request until the request is aborted. This may be used when sending Beacon or Claim frames.</p> <p>0: Fetch all frames of REQ. 1: Repeat transmission of first frame of REQ.</p> <p>A Request may use Repeat on RCHN1, and have a Request loaded on RCHN0, but not vice-versa. Specifically, when a Request with the Repeat option is loaded on RCHN0, RCHN1 must not have any REQs active or visible to the MACSI device. Thus REQs on RCHN1 may be queued externally but the queue's Limit Register must not be set at or after that point. Requests with the Repeat option should only be used on one Request Channel at a time, and preferably on RCHN0.</p> <p>Note that the Repeat Option requires a REQ.First Descriptor. The Repeat Option will not work on a REQ.Only Descriptor.</p>
D23–D16	SIZE	<p>Size: Count of number of frames represented by the ODUD stream pointed to by REQ.LOC field. Descriptors with a null frame count are permitted, and are typically used to end a Request, without having to send data. For example, to end a restricted dialogue, a REQ.Last with SIZE = 0 will cause the Request Machine to command the Ring Engine to capture and release the specified classes of token. The response of the MACSI device to REQs with SIZE = 0 is as follows:</p> <ol style="list-style-type: none"> 1. REQ.First: MACSI device latches the REQ Descriptor fields, then fetches the next REQ. RQRCLS is asserted, but RQRDY remains deasserted. 2. REQ.Middle: MACSI device fetches the next REQ. 3. REQ.Only: MACSI device requests the capture of the appropriate token. When it is captured, the MACSI device asserts RQFINAL and ends the request. 4. REQ.Last: MACSI device captures the token, asserts RQFINAL, then marks the request complete.
D29–D24	UID	User Identification: Contains the UID field from the current REQ.First or REQ.Only.
D31–D30	RES	Reserved
Word 1		
D27–D0	LOC	Location: Bits [27:2] are the memory word address of the ODUD stream. Bits [1:0] are expected to be 00, and are not checked.
D29–D28	RES	Reserved
D31–D30	F-L	First/Last Tag: Identifies the REQ stream part, i.e., Only, First, Middle, or Last. FL = 10 = First, FL = 00 = Middle, FL = 01 = Last, FL = 11-Only.

1111	RcntD	Restricted	D	restr	restr	2

E = enabled, D = disabled, non-r = non-restricted, restr = restricted, capt = captured

Note 1: Synchronous Requests are not serviced when bit BCNR of the Ring Event Latch Register is set.

Note 2: Restricted Requests are not serviced when bit BCNR, CLMR, or OTRMAC of the Ring Event Latch Register is set.

Note 3: Restricted Dialogues only begin when a Non-Restricted token has been received and transmitted.

Note 4: Immediate Requests are serviced when the ring is Non-Operational. These requests are serviced from the Data state unless the Request contains a Beacon or Claim FC. If a Claim FC is used, Immediate Requests are serviced from the Claim State. If a Beacon FC is used, Immediate Request are serviced from the Beacon State.

FIGURE 7-7. REQ Descriptor Confirmation Class Field Encodings

7.0 Control Information (Continued)

Output Data Unit Descriptor (ODUD)

An Output Data Unit Descriptor (ODUD) contains the part, byte address and size of an Output Data Unit. During Request operations, ODUDs are fetched by the MACSI device from a list in memory, using the address in the ODUD List Pointer Register (in the Pointer RAM).

ODUD.Firsts and ODUD.Middles may have a zero byte count, which is useful for fixed protocol stacks. One layer may be called, and if it has no data to add to the frame, it may add an ODUD with a zero byte count to the list. ODUD.Onlys and ODUD.Last may not have a zero byte count.

The MACSI device checks for the following inconsistencies when an ODUD is loaded from memory:

1. ODUD.First, when previous ODUD was not an ODUD.Last or ODUD.Only.
2. ODUD which is not an ODUD.First, when the previous ODUD was ODUD.Last or ODUD.Only.
3. ODUD.Last or ODUD.Only with a zero byte count.

When an inconsistency is detected, the MACSI device aborts the Request, and reports the exception in the Request Status field of the CNF Descriptor.

The entire ODUD object must contain at least 4 bytes (for short addresses).

Bit	Symbol	Description
Word 0		
D12–D0	CNT	Byte Count: Number of bytes in the ODU. For an ODUD.First or ODUD.Middle the size may be Zero, which is useful for fixed protocol stacks.
D31–D13	RES	Reserved
Word 1		
D27–D0	LOC	Location: Pointer to the first byte of the corresponding ODU.
D29–D28	RES	Reserved
D31–D30	F-L	First/Last Tag: Identifies the Output Data Unit part, i.e., Only, First, Middle, or Last. FL = 10 = First, FL = 00 = Middle, FL = 01 = Last, FL = 11-Only.

7.0 Control Information (Continued)

Confirmation Status Message Descriptor (CNF)

A Confirmation Status Message (CNF) describes the result of a Request operation.

A more detailed description of the encoding of the RS bits is given in *Figure 7-8*.

31	30	29	28	27	24	23	16	15	8	7	0

7.0 Control Information (Continued)

Bit	Symbol	Description
Word 1		
D7–D0	RES	Reserved
D15–D8	CS	Confirmation Status
D9–D8	FT	Frame Type: This field reflects the type of frame that ended Full Confirmation. 00: Any Other. 01: Token. 10: Other Void. 11: My Void.
D10	F	Full Confirm: This bit is set when the Request was for Full Confirmation.
D11	U	Unexpected Frame Status: This bit is set when the frame status does not match the value programmed in the Request Expected Frame Status Register. This applies only to Full Confirmation.
D12	P	Parity: This bit is set when a parity error is detected in a received frame. Parity is checked from FC to ED inclusive if the FLOW bit in the Mode Register is set.
D13	E	Exception: This bit is part of the MACSI's hierarchical status reporting. It is set when an exception occurs during confirmation. An exception is any one of the nine error or exception codes described in the RS Field. The RCHN's EXC bit in the Request Attention Register is also set.
D14	R	Ring-Op: This bit is set when the ring changes operational state after transmission but before all returning frames have been confirmed.
D15	T	Transmit Class: 0: Restricted. 1: Non-Restricted.
D23–D16	FC	Frame Control: Frame Control field of the last frame of the last confirmed burst. Valid only for Full Confirmation.
D29–D24	UID	User Identification: Contains the UID field copied from the current REQ.First or REQ.Only.
D31–D30	F-L	First/Last Tag: Identifies the CNF part, i.e., Only, First, Middle, or Last. FL = 10 = First, FL = 00 = Middle, FL = 01 = Last, FL = 11-Only.

7.0 Control Information (Continued)

INTERMEDIATE

[0000]	NONE: Non status is written. This may be used by software to identify a NULL or invalid CNF.
[0001]	Preempted: RCHN1 was preempted by RCHN0. RCHN1 will be serviced following RCHN0.
[0010]	Part None: The MACSI device is servicing a Request, but it cannot hold onto a token, and the last frame of a Request.part has been transmitted.

BREAKPOINTS

[0011]	Service Loss: The THT expired during a Request with THT enabled. Only Occurs for Intermediate Confirmation.
[0100]	Reserved

COMPLETION

[0101]	Completed Beacon: When transmitting from the Beacon state, this status is returned when the Ring Engine receives a My__Beacon. When transmitting from the Claim state, this status is returned when the Ring Engine wins the Claim process.
[0110]	Completed OK: Normal completion with good status.

EXCEPTION COMPLETION:

In all of the exception and error cases it is likely that at least some of the frames from the associated request were not transmitted properly. Therefore, retransmission may be required. In the case of bad confirmation [0111], the frames may have been transmitted properly but lost on the ring. A consistency failure [1110] means that there is a problem in the request queues. It is recommended that they be reinitialized. The Internal or Abus error code [1111] is very severe and it recommended that the MACSI device be reinitialized.

[0111]	Bad Confirmation: This status is reported when there was an error during confirmation. For confirmation, the MACSI device compares the returning frame to the Expected Frame Status (EFS). If these values do not match, the "Bad Confirmation" value is returned in the RS field. If the transmitted frame does not return, (My__Void, Other__Void, or Token received instead) or if the ring state changes, (MAC Reset or the Ring__Operational flag changes), the Bad Confirmation value is also returned.
[1000]	Underrun: This exception is caused when the memory interface does not allow the MACSI device to fill the transmit data FIFO as quickly as it is being emptied. It implies that the frame was aborted during transmission.
[1001]	Host Abort: This exception is caused when the host software clears the SAR.ABT bit to force an abort or when there is not enough space in the confirmation (CNF) queue. This implies that the Request did not complete normally.
[1010]	Bad Ringop: This exception is reported when the Request Class for a Request object is incompatible with the current ring state, (i.e. Immediate class with an operational ring or Async, Sync, or restricted class when the ring state is non-operational). The Request was aborted.
[1011]	MAC Device Abort: This exception indicates that the MACSI device aborted the Request and asserted TXABORT. This could be from an interface parity error, or because the transmitted frame failed the FC check, or because the MACSI device received a MAC frame while transmitting in the DATA state. This status is also returned when the MACSI device receives an Other__Beacon while transmitting in the Beacon state, or when the Claim process is lost while transmitting in the Claim state. It implies that the Request did not complete normally.
[1100]	Timeout: This exception code indicates that the TRT timer expired during the transmission of a Request with THT disabled. Normally the Ring Engine will finish the current frame and release the Token when the Token Holding Timer (THT) expires. However, for certain requests, the THT can be disabled. In this case, the Token Rotation Timer (TRT) may expire because the station has made the Token Late. The Ring Engine will abort the request and a Timeout will be signaled to the System Interface.
[1101]	MAC Reset: This code indicates that the MACSI underwent a MAC Reset during this request. A MAC Reset can be generated by software, (i.e. requested via the control bus), or caused by hardware, (the MACSI state machines entered and illegal state). In either case the Request is aborted.
[1110]	Consistency Failure: This code indicates that the MACSI device detected an inconsistency in the REQ or ODUD descriptor queues. For example, if a frame started with an ODUD.First it should be followed by an ODUD.Middle or ODUD.Last. If the next ODUD was another ODUD.First this would be a consistency error. The Request is aborted when a consistency error is detected.

ERROR

[1111]	Internal or Fatal ABus Error: This exception is caused when the MACSI device detects an internal hardware error (e.g. illegal state machine state), in the transmit logic while transmitting a frame. It is also set when an ABus error occurs during frame transmission. It implies that the frame data may not have been transmitted properly.
--------	---

FIGURE 7-8. Request Status Field (RS) of CNF Descriptor

7.0 Control Information (Continued)

Pool Space Descriptor (PSP)

Pool Space Descriptors (PSPs) contain the address of a free space in host memory available for writing Input Data Units. The count field is not used. The space is assumed to end at the next 4 kByte boundary. When PSPs are read by the MACSI device, the address field of the PSP is loaded into the Indicate Channel's IDU Pointer Register, and is used as the address for the IDU memory write.

Bit	Symbol	Description
Word 0		
D12–D0	CNT	Byte Count: Number of bytes of available memory area (this field is currently not used by the MACSI device). To ensure software compatibility with future devices which may use this field, this field may be written with the number of bytes from PSP.LOC to the next 4 kByte boundary.
D31–D13	RES	Reserved
Word 1		
D27–D0	LOC	Location: Memory byte address of memory area available for writing IDUs. Normally the page offset will be Zero to simplify space management. Must be burst aligned to the size of the largest burst enabled (4 word or 8 word).
D29–D28	RES	Reserved
D31–D30	F-L	First/Last Tag: Identifies the PSP part, should be PSP.Only (i.e F-L = 11).

8.0 Signal Descriptions

The DP83266 MACSI device is packaged in a 160-pin Plastic Quad Flat Pack. The signals are divided into the following interfaces:

Control Interface:	Used for microprocessor access to the Ring Engine and Service Engine.
PHY Interface:	Interface signals to the DP83251/55 PLAYER or DP83256/57 PLAYER+.
External Matching Interface:	Interface signals used for external address matching.
LED Interface:	Used to control status LEDs.
ABus Interface:	Multiplexed Address/Data System Interface.
Electrical Interface:	Signals associated with power supply and clocking.

8.1 CONTROL INTERFACE

The Control Interface operates asynchronously to the operation of the data services. During an access, the external Control Bus is synchronized with the internal Control Bus.

The ACK and INT signals are open drain signals to allow a wired-OR connection of several such signals.

Symbol	Pin #	I/O	Description
CBP	155	I/O	Control Bus Parity: Odd parity on CBD7–0.
CBD7–0	154–147	I/O	Control Bus Data: Bidirectional Data bus.
CBA8–0	144–136	I	Control Bus Address: Address of a particular MACSI device register.
\overline{CE}	130	I	Control Bus Enable: Handshake signal used to begin a Control Interface access. Active low signal.
R/ \overline{W}	129	I	Read/Write: Determines current direction of a Control Interface access.
\overline{ACK}	133	OD	Acknowledge: Acknowledges that the Control Interface access has been performed. Active low, open drain signal.
$\overline{INT1-0}$	131, 132	OD	Interrupt: Indicates presence of one or more enabled conditions in the Event Registers. One Interrupt signal is provided as an indication to management services and one is provided as an indication to data services. These can be tied together externally to create a single interrupt signal if desired. Active low, open drain signal.

8.0 Signal Descriptions (Continued)

8.2 PHY INTERFACE

The PHY Interface signals transfer symbol pairs between the MACSI and PLAYER+ devices. Transfers are synchronous using the 12.5 MHz Local Byte Clock signal (signal provided by the PLAYER+ device).

A control bit is used to indicate if a Data symbol pair or Control symbol pair or a mixed Control/Data symbol pair are being transferred.

Parity is generated on the PH__Indicate and MA__Indicate data. Parity is checked on the PH__Request and MA__Request data.

Symbol	Pin #	I/O	Description
PRP	122	O	PHY Request Parity: Odd parity for PRC and PRD7–0.
PRC	120	O	PHY Request Control: 0: Indicates PRD7–0 contains a Data symbol pair. 1: Indicates PRD7–0 contains a Control or mixed Control/Data symbol pair.
PRD7–PRD0	118, 116, 114, 110, 108, 106, 104, 102	O	PHY Request Data: Contains a Data or Control symbol pair.
PIP	123	I	PHY Indicate Parity: Odd parity for PIC and PID7–0.
PIC	121	I	PHY Indicate Control: 0: Indicates PRD7–PRD0 contains a Data symbol pair. 1: Indicates PRD7–PRD0 contains a Control or mixed Control/Data symbol pair.
PID7–PID0	119, 117, 115, 111, 109, 107, 105, 103	I	PHY Indicate Data: Contains a Data or a mixed Control/Data symbol pair.

8.0 Signal Descriptions (Continued)

8.2.1 PHY Interface Codes

The DP83256/57 PLAYER+ device converts the Standard 4B/5B FDDI symbol code to the internal code used at the PHY Interface. The PH_DATA.Indication table shows how the Ring Engine interprets the codes generated by the PLAYER+ device and the PH_DATA.Request table shows the codes generated by the Ring Engine.

The internal code is actually an 8B/9B code with parity where one bit is used to determine whether the symbol pair contains two data symbols or at least one control symbol.

PH_DATA.Indication

The Ring Engine interprets the byte stream the PLAYER+ device as defined in Table 8-1.

TABLE 8-1. Internal PHY Indicate Coding

Value	PIP	PIC	PID(7-4)	PID(3-0)	Type
0	1	0	0000	0000	Data Symbol Pair
1	0	0	0000	0001	Data Symbol Pair
:	:	:	:	:	:
254	0	0	1111	1110	Data Symbol Pair
255	1	0	1111	1111	Data Symbol Pair
JK	P	1	1101	xxxx	Start Delimiter
PI	P	1	x011	x1xx	PH_Invalid
PI	P	1	x011	xx1x	PH_Invalid
II	P	1	10xx	xxxx	Idle Symbols
nl	P	1	0000	10xx	Data/Idle Symbol
RR	P	1	0110	0110	Frame Status
RS	P	1	0110	0111	Frame Status
RT	P	1	0110	0101	Frame Status
SS	P	1	0111	0111	Frame Status
SR	P	1	0111	0110	Frame Status
ST	P	1	0111	0101	Frame Status
SX	P	1	0111	xxxx	Frame Status
TX	P	1	0101	xxxx	Ending Delimiter
TR	P	1	0101	0110	Ending Delimiter
TS	P	1	0101	0111	Ending Delimiter
TT	P	1	0101	0101	Ending Delimiter
nT	P	1	0000	0101	Mixed Symbol Pair
Parity Error	\bar{P}	0	????	????	Code Violation
Other wise	?	1	Else		Code Violation

where:

PIP PHY Indicate Parity bit, ODD parity

PIC PHY Indicate Control bit:

0 ≥ data byte,

1 ≥ control/mixed byte

PID(7-0) PHY Indicate Data(7-0)

P represents ODD Parity (~ \bar{P} is Bad Parity)

x – represents a don't care and is not decoded

? represents a 1 or 0 but not both.

The PLAYER aligns the received JK to a byte boundary. Thus, no provision is made in the internal code or by the Ring Engine for off boundary JKs.

8.0 Signal Descriptions (Continued)

The Idle and PH_Invalid encodings overlap. Idle symbols received while the PLAYER+ device is in Active Line State (ALS) or Idle Line State (ILS) are not considered PH_INVALID. Idle symbols received while the PLAYER+ device is in states other than ALS or ILS are treated as PH_Invalid.

PH_DATA.Request

The Ring Engine generates the 10-bit byte stream as defined in Table 8-2. Note that all symbol pairs are either control or data symbol pairs. Mixed data/control symbol pairs are never generated or repeated by the Ring Engine.

TABLE 8-2: Internal PHY Request Coding

Value	PRP	PRC	PRD(7-4)	PRD(3-0)	Type
0	1	0	0000	0000	Data Symbol Pair
1	0	0	0000	0001	Data Symbol Pair
:	:	:	:	:	:
254	0	0	1111	1110	Data Symbol Pair
255	1	0	1111	1111	Data Symbol Pair
JK	0	1	1101	1101	Start Delimiter
II	0	1	1010	1010	Idle Symbols
RR	0	1	0110	0110	Frame Status
RS	1	1	0110	0111	Frame Status
RT	0	1	0110	0101	Frame Status
SS	0	1	0111	0111	Frame Status
SR	1	1	0111	0110	Frame Status
ST	1	1	0111	0101	Frame Status
TR	0	1	0101	0110	Ending Delimiter
TS	1	1	0101	0111	Ending Delimiter
TT	0	1	0101	0101	Ending Delimiter

Where:

PRP — PHY Request Parity bit, parity for all symbol pairs is ODD

PRC — PHY Request control bit:

0 ≥ data byte

1 ≥ control byte

PRD(7-0) PHY Request Data (7-0)

The Ring Engine can repeat the RT and ST symbol pairs but will not generate them.

8.0 Signal Descriptions (Continued)

8.3 EXTERNAL MATCHING INTERFACE

The External Matching Interface provides the means to add external address recognition logic. The results of these address comparisons are conveyed on the appropriate signals.

Symbol	Pin #	I/O	Description
ECIP	86	I	External Compare In Progress: This signal is asserted to indicate that external address comparison has begun. It is deasserted to indicate that the comparison has completed. ECOPI and EM are sampled on the rising edge of LBC1 after the deassertion of ECIP. ECIP must be asserted before the seventh byte of the INFO field in order for the MACSI device to recognize an external comparison. It must be deasserted for at least one cycle for the external comparison to complete. If ECIP has not been deasserted before two bytes after the End Delimiter (ED, from the PLAYER + device), the MACSI device will not copy this frame. ECIP may be implemented as a positive or negative pulse. Note that ECIP will affect the operation of the MACSI device even if the external copy mode is not specifically selected. See Section 6.3 on page 30 for more details on the external matching interface.
ECOPI	84	I	External Copy: Indicates that the current frame should be copied, if possible. Sampled on the rising edge of LBC1 after ECIP is deasserted.
EA	85	I	External Destination Address Match: Indicates that an explicit match occurred on the current frame. This affects the setting of the A indicator for this frame. Sampled one byte time before ED is received by the Ring Engine.
EM	87	I	External Source Address Match: Indicates that the current frame was transmitted by this station and should be stripped. The Ring Engine will begin stripping three byte times after the assertion of EM. The Service Engine samples EM on the rising edge of LBC1 after the deassertion of ECIP.
LEARN	90	O	Learn: Provided for transparent bridging applications. Indicates that the current frame should be copied and the Source Address be added to the address filter database if not already present. This signal is asserted for Long Address frames which were not sourced by this station. If frames are sent using Source Address Transparency (SAT) using the My_Void stripping mechanism, Learn will be false from the transmission of the first SAT frame until after the My_Void frame is received. Learn is valid at the "INFO Received" point for each frame. This is when the fourth byte of INFO field passes between the Ring Engine and the System Interface. This occurs three byte-times after the fourth byte of the INFO field passes between the PLAYER + device and the MACSI device.
AFINHIB	26	I	AFLAG Inhibit: For MACSI Revision D or later, this pin allows the User to suppress internal address recognition on individual frames. By asserting this pin before the 7th byte of the INFO field (as measured at the PID interface), the User can block the AFLAG signal between the MAC and the System Interface. For the MACSI to recognize this pin, the User must assert the MAC Mode Register 2, AFLAG Inhibit Enable bit (MCMR2.AFIE). For MACSI Revision prior to D, this is a No Connect pin.

8.4 LED INTERFACE

These signals provide a means for controlling status LEDs to give a visual indication of transmit and receive activity. Since the LED control pins use open-drain output structures, the User must supply pull-up resistors. This interface is only available on MACSI Revision D or later.

Symbol	Pin #	I/O	Description
TXLED	98	OD	Transmit LED: The MACSI will assert this pin when it detects that the Request State machine has entered the "sending" state, (once per transmitted frame). Note that the MACSI device will not assert TXLED for internally generated MAC frames. This pin will not drive an LED directly. The User must supply a one-shot circuit to create a pulse long enough to make the LED visible.
RXLED	99	OD	Receive LED: The MACSI will assert this pin when it detects the End Delimiter of a copied frame (VCOPY and EDRCVD). This pin will not drive an LED directly. The User must supply a one-shot circuit to create a pulse long enough to make the LED visible.

8.0 Signal Descriptions (Continued)

8.5 ABus INTERFACE

The ABus interface signals provide a 28-bit address 32-bit data bus for transfers between the host system and the MACSI device. The ABus uses a bus request/bus grant protocol that allows for multiple bus masters, supports burst transfers of 4 or 8 32-bit words, and permits both physical and virtual addressing using fixed-size pages.

Address and Data:

Symbol	Pin #	I/O	Description																																		
AB_BP3-0	50, 61, 72, 83	I/O	ABus Byte Parity: These TRI-STATE signals contain the parity for each address and data byte of AB_AD, such that AB_BP0 is the parity for AB_AD7-0, AB_BP1 is the parity for AB_AD15-8, etc.																																		
AB_AD31-0	40-42, 45-49, 51-53, 56-60, 62-65, 68-71, 73-76, 79-82	I/O	<p>ABus Address and Data: These TRI-STATE signals are the multiplexed ABus address and data lines. During the address phase of a cycle, AB_AD27-0 contain the 28-bit address. When SIMR1.EAM = 1, AB_AD31-28 contain a value specified by the user (by programming SIMR1.AB_A31-27) during the address cycle. When SIMR1.EAM = 0, AB_AD31-28 contain a 4-bit function code identifying the type of transaction, encoded as follows:</p> <table border="1"> <thead> <tr> <th>AB_AD[31:28]</th> <th>Transaction Type</th> </tr> </thead> <tbody> <tr><td>0</td><td>RCHN1 ODU Load</td></tr> <tr><td>1</td><td>RCHN1 ODUD Load/CNF Store</td></tr> <tr><td>2</td><td>RCHN1 REQ Load</td></tr> <tr><td>3</td><td>RCHN0 ODU Load</td></tr> <tr><td>4</td><td>RCHN0 ODUD Load/CNF Store</td></tr> <tr><td>5</td><td>RCHN0 REQ Load</td></tr> <tr><td>6</td><td>ICHN2 IDU Store</td></tr> <tr><td>7</td><td>ICHN2 IDUD Store</td></tr> <tr><td>8</td><td>ICHN2 PSP Load</td></tr> <tr><td>9</td><td>ICHN1 IDU Store</td></tr> <tr><td>A</td><td>ICHN1 IDUD Store</td></tr> <tr><td>B</td><td>ICHN1 PSP Load</td></tr> <tr><td>C</td><td>ICHN0 IDU Store</td></tr> <tr><td>D</td><td>ICHN0 IDUD Store</td></tr> <tr><td>E</td><td>ICHN0 PSP Load</td></tr> <tr><td>F</td><td>PTR RAM Load/Store</td></tr> </tbody> </table>	AB_AD[31:28]	Transaction Type	0	RCHN1 ODU Load	1	RCHN1 ODUD Load/CNF Store	2	RCHN1 REQ Load	3	RCHN0 ODU Load	4	RCHN0 ODUD Load/CNF Store	5	RCHN0 REQ Load	6	ICHN2 IDU Store	7	ICHN2 IDUD Store	8	ICHN2 PSP Load	9	ICHN1 IDU Store	A	ICHN1 IDUD Store	B	ICHN1 PSP Load	C	ICHN0 IDU Store	D	ICHN0 IDUD Store	E	ICHN0 PSP Load	F	PTR RAM Load/Store

AB_A27-2	25-19, 16-5, 2-1, 160-156	O	ABus Demultiplexed Address: These TRI-STATE signals contain the word address during ABus accesses. They are driven from Tpa to the last Td state, negated in the following Tr state, then released. Note that the timing of these signals is under software control via the System Interface Mode Register 1 (SIMR1). For MACSI revision A through C, the User must set SIMR1.ATM to one for the demultiplexed address pins AB_A (27:2) to work properly. For MACSI revision D and later (SI revision \geq 0x00000058), the User may use the demultiplexed address pins AB_A (27:2) with SIMR1.ATM set to one or zero. Since the MACSI device makes only word (4 byte) accesses on the ABus, the device does not include pins for AB_A (1:0). These pins would drive a zero for every access.																																		

8.0 Signal Descriptions (Continued)

Bus Control:

Symbol	Pin #	I/O	Description																																																											
$\overline{AB_AS}$	39	O	ABus Address Strobe: When first asserted, this TRI-STATE signals indicates that address on AB_AD is valid. When this signal is inactive and $\overline{AB_ACK}$ is asserted, the next cycle is a Recovery State (Tr), in which the bus arbiter can sample all bus requests, then issue a bus grant in the following cycle. Note that the timing of this signal is under software control via Mode Register 1 (MR1).																																																											
AB_R/ \overline{W}	35	O	ABus Read/Write: This TRI-STATE signal determines the current direction of an ABus access. A high level indicates a read access and a low level indicates a write access.																																																											
$\overline{AB_DEN}$	34	I/O	ABus Data Enable: In normal ABus mode, this TRI-STATE signal indicates that data on AB_AD31-0 is valid. In the enhanced ABus mode for SBus, this signal is an additional Acknowledgment input.																																																											
AB_SIZ2-0	31-29	O	<p>ABus Size: These TRI-STATE signals indicate the size of the transfer on AB_AD31-0, encoded as follows:</p> <table border="1"> <thead> <tr> <th>AB_SIZ2</th> <th>AB_SIZ1</th> <th>AB_SIZ0</th> <th>Transfer Size</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>4 Bytes</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>Reserved</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>Reserved</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>Reserved</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>16 Bytes</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>32 Bytes</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>Reserved</td> </tr> <tr> <td>1</td> <td>1</td> <td>1</td> <td>Reserved</td> </tr> </tbody> </table>	AB_SIZ2	AB_SIZ1	AB_SIZ0	Transfer Size	0	0	0	4 Bytes	0	0	1	Reserved	0	1	0	Reserved	0	1	1	Reserved	1	0	0	16 Bytes	1	0	1	32 Bytes	1	1	0	Reserved	1	1	1	Reserved

1	1	0	Reserved																																																											
1	1	1	Reserved																																																											
$\overline{AB_ACK}$	37	I	ABus Acknowledge: Indicates a bus slave's response to a bus master. The meaning of this signal depends on the state of ABus Error ($\overline{AB_ERR}$) as well as the ABus mode selected (normal or enhanced). The exact function is described below.																																																											
$\overline{AB_ERR}$	36	I	<p>ABus Error: In normal ABus mode, this signal is asserted by a bus slave to cause a transaction retry or transaction abort. In the enhanced ABus mode for SBus, this signal together with $\overline{AB_ACK}$ and $\overline{AB_DEN}$ encode the acknowledgment type. The encoding is as follows:</p> <table border="1"> <thead> <tr> <th colspan="2">EAM = 0</th> <th colspan="3">EAM = 1</th> <th rowspan="2">Function</th> </tr> <tr> <th>$\overline{AB_ACK}$</th> <th>$\overline{AB_ERR}$</th> <th>$\overline{AB_ACK}$ Ack(2)*</th> <th>$\overline{AB_DEN}$ Ack(1)*</th> <th>$\overline{AB_ERR}$ Ack(0)*</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>1</td> <td>1</td> <td>1</td> <td>1</td> <td>Wait Cycle</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>1</td> <td>1</td> <td>Word Acknowledgement</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>0</td> <td>0</td> <td>Retry</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>1</td> <td>0</td> <td>Error</td> </tr> <tr> <td></td> <td></td> <td>0</td> <td>0</td> <td>0</td> <td>Not Supported</td> </tr> <tr> <td></td> <td></td> <td>0</td> <td>0</td> <td>1</td> <td>Not Supported</td> </tr> <tr> <td></td> <td></td> <td>0</td> <td>1</td> <td>0</td> <td>Not Supported</td> </tr> <tr> <td></td> <td></td> <td>1</td> <td>0</td> <td>1</td> <td>Not Supported</td> </tr> </tbody> </table>	EAM = 0		EAM = 1			Function	$\overline{AB_ACK}$	$\overline{AB_ERR}$	$\overline{AB_ACK}$ Ack(2)*	$\overline{AB_DEN}$ Ack(1)*	$\overline{AB_ERR}$ Ack(0)*	1	1	1	1	1	Wait Cycle	0	1	0	1	1	Word Acknowledgement	0	0	1	0	0	Retry	1	0	1	1	0	Error			0	0	0	Not Supported			0	0	1	Not Supported			0	1	0	Not Supported			1	0	1	Not Supported

Bus Arbitration:

Symbol	Pin #	I/O	Description
$\overline{AB_BR}$	28	O	ABus Bus Request: This signal is used by the MACSI device to request use of the ABus.
$\overline{AB_BG}$	27	I	ABus Grant: This signal is asserted by external bus arbitration logic to grant use of the ABus to the MACSI device. If $\overline{AB_BG}$ is asserted at the start of a transaction (Tbr), the MACSI device will run a transaction. Note that in normal ABus mode (MR1.EAM = 0), the MACSI device may take up to two cycles to respond to $\overline{AB_BG}$. Therefore, $\overline{AB_BG}$ should not be removed until the MACSI device has indicated that it has sampled $\overline{AB_BG}$ and taken the bus, (this can be determined with $\overline{AB_AS}$ for example).
$\overline{AB_CLK}$	38	I	ABus Clock: All ABus operations are synchronized to the rising edge of $\overline{AB_CLK}$.

8.0 Signal Descriptions (Continued)

8.6 ELECTRICAL INTERFACE

Symbol	Pin #	I/O	Description
LBC5, 3	125, 126	I	Local Byte Clock: 12.5 MHz clocks with a 50/50 duty-cycle, generated by the PLAYER+ device.
LBC1	127	I	Local Byte Clock: 12.5 MHz clock with a 50/50 duty-cycle, generated by the PLAYER+.
LSC	124	I	Local Symbol Clock: 25 MHz clock with a 40/60 duty-cycle, generated by the PLAYER+ device.
$\overline{\text{RST}}$	128	I	Reset: Active Low input which resets the Internal State Machines and most Registers. This signal must be asserted for at least five clock cycles. When asserted, all bidirectional signals are at TRI-STATE.
TCK	95	I	TCK: JTAG Scan Clock
TMS	94	I	TMS: JTAG Mode Select
TDI	93	I	TDI: JTAG Data In
TDO	92	O	TDO: JTAG Data Out
$\overline{\text{TRST}}$	91	I	TRST: JTAG Reset. Active low signal.
V _{CC} [11]	3, 17, 32, 43, 54, 66, 77, 97, 113, 135, 146		Positive Power Supply: 5V, 10% relative to GND.
GND[11]	4, 18, 33, 44, 55, 67, 78, 96, 112, 134, 145		Ground: Power Supply Return.
RSRVD0	88, 100, 101	I	Reserved 0: Must be connected to ground.
N/C	89		No Connect: Must be left unconnected.

9.0 Electrical Characteristics

9.1 ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Conditions	Min	Typ	Max	Units
V _{CC}	Supply Voltage		-0.5		7.0	V
DC _{IN}	Input Voltage		-0.5		V _{CC} + 0.5	V
DC _{OUT}	Output Voltage		-0.5		V _{CC} + 0.5	V
T _{STG}	Storage Temperature		-65		150	°C
T _L	Lead Temperature	Soldering, 10 Sec. (IR or Vapor) (Phase Reflow)			230	°C
	ESD Protection		2000			V

9.2 RECOMMENDED OPERATING CONDITIONS

Symbol	Parameter	Conditions	Min	Typ	Max	Units
V _{CC}	Supply Voltage		4.75		5.25	V
T _A	Operating Temperature		0		70	°C
PD	Power Dissipation	C _L = 50 pf, LBC = 12.5 MHz, AB_CLK = 25 MHz			945	mW

9.3 DC ELECTRICAL CHARACTERISTICS

The DC characteristics are over the operating range, unless otherwise specified.

Symbol	Parameter	Conditions	Min	Typ	Max	Units
V _{OH}	Output High Voltage	I _{OH} = -8 mA	2.4			V
V _{OL1}	Output Low Voltage	I _{OL} = 8 mA			0.4	V
V _{OL2}	Output Low Voltage for $\overline{\text{INT0}}$, $\overline{\text{INT1}}$, and $\overline{\text{ACK}}$ (open drain)	I _{OL} = 8 mA			0.4	V
V _{IH}	Input High Voltage		2.0			V
V _{IL}	Input Low Voltage				0.8	V
I _{IL}	Input Low Current	V _{IN} = GND			-10	μA
I _{IH}	Input High Current	V _{IN} = V _{CC}			+10	μA
I _{OZ1}	TRI-STATE Leakage				±10	μA
I _{OZ2}	TRI-STATE Leakage for $\overline{\text{INT0}}$, $\overline{\text{INT1}}$, and $\overline{\text{ACK}}$ (open drain)				±10	μA
I _{CC}	Dynamic Supply Current	C _L = 50 pf, LBC = 12.5 MHz, AB_CLK = 25 MHz			180	mA

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied and National reserves the right at any time without notice to change said circuitry and specifications.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
